Abstract

OpenShift Installation and Configuration topics cover the basics of installing and configuring OpenShift in your environment. Use these topics for the one-time tasks required to get OpenShift up and running.

Table of Contents

CHAPTER 1. OVERVIEW	18
CHAPTER 2. INSTALLING A CLUSTER	19
2.1. PLANNING	19
2.1.1. Initial Planning	19
2.1.2. Installation Methods	19
2.1.3. Sizing Considerations	19
2.1.4. Environment Scenarios	20
2.1.4.1. Single Master and Multiple Nodes	20
2.1.4.2. Single Master, Multiple etcd, and Multiple Nodes	21
2.1.4.3. Multiple Masters Using Native HA	21
2.1.4.4. Stand-alone Registry	22
2.1.5. RPM vs Containerized	22
2.2. PREREQUISITES	22
2.2.1. System Requirements	22
2.2.1.1. Red Hat Subscriptions	22
2.2.1.2. Minimum Hardware Requirements	22
2.2.1.3. Production Level Hardware Requirements	23
2.2.1.4. Configuring Core Usage	24
2.2.1.5. SELinux	25
2.2.1.6. NTP	25
2.2.1.7. Security Warning	25
2.2.2. Environment Requirements	25
2.2.2.1. DNS	26
2.2.2.1.1. Configuring Hosts to Use DNS	26
2.2.2.1.2. Disabling dnsmasq	27
2.2.2.1.3. Configuring a DNS Wildcard	28
2.2.2.2. Network Access	28
2.2.2.2.1. NetworkManager	28
2.2.2.2. Required Ports	28
2.2.2.3. Persistent Storage	31
2.2.2.4. Cloud Provider Considerations	31
2.2.2.4.1. Configuring a Security Group	31
2.2.2.4.2. Overriding Detected IP Addresses and Host Names	32
2.2.2.4.3. Post-Installation Configuration for Cloud Providers	34
2.3. HOST PREPARATION	34
2.3.1. Operating System Requirements	34
2.3.2. Host Registration	34
2.3.3. Installing Base Packages	35
2.3.4. Installing Docker	36
2.3.5. Configuring Docker Storage	37
2.3.5.1. Reconfiguring Docker Storage	40
2.3.5.2. Managing Container Logs	41
2.3.5.3. Viewing Available Container Logs	41
2.3.6. Ensuring Host Access	42
2.3.7. What's Next?	42
2.4. INSTALLING ON CONTAINERIZED HOSTS	42
2.4.1. Overview	42
2.4.2. Install Methods for Containerized Hosts	43
2.4.3. Required Images	43
2.4.4. CLI Wrappers	44
•••	

2.4.5. Starting and Stopping Containers	44
2.4.6. File Paths	45
2.4.7. Storage Requirements	45
2.4.8. Open vSwitch SDN Initialization	45
2.5. QUICK INSTALLATION	45
2.5.1. Overview	45
2.5.2. Before You Begin	46
2.5.3. Running an Interactive Installation	47
2.5.4. Defining an Installation Configuration File	47
2.5.5. Running an Unattended Installation	49
2.5.6. Verifying the Installation	49
2.5.7. Uninstalling OpenShift Container Platform	50
2.5.8. What's Next?	51
2.6. ADVANCED INSTALLATION	51
2.6.1. Overview	51
2.6.2. Before You Begin	51
2.6.3. Configuring Ansible Inventory Files	52
Image Version Policy	52
2.6.3.1. Configuring Cluster Variables	52
2.6.3.2. Configuring Deployment Type	56
2.6.3.3. Configuring Host Variables	56
2.6.3.4. Configuring Master API and Console Ports	58
2.6.3.5. Configuring Cluster Pre-install Checks	59
2.6.3.6. Configuring System Containers	60
2.6.3.6.1. Running Docker as a System Container	61
2.6.3.6.2. Running etcd as a System Container	62
2.6.3.7. Configuring a Registry Location	63
2.6.3.8. Configuring Global Proxy Options	63
2.6.3.9. Configuring the Firewall	65
2.6.3.10. Configuring Schedulability on Masters	65
2.6.3.11. Configuring Node Host Labels	65
2.6.3.11.1. Configuring Dedicated Infrastructure Nodes	66
2.6.3.12. Configuring Session Options	66
2.6.3.13. Configuring Custom Certificates	67
2.6.3.14. Configuring Certificate Validity	68
2.6.3.15. Configuring Cluster Metrics	68
2.6.3.15.1. Configuring Metrics Storage	69
Option A: NFS Host Group	69
Option B: External NFS Host	69
Option C: Dynamic	69
2.6.3.16. Configuring Cluster Logging	69
2.6.3.16.1. Configuring Logging Storage	70
Option A: NFS Host Group	70
Option B: External NFS Host	70
Option C: Dynamic	70
2.6.4. Single Meeter Freezeles	71
2.6.4.1. Single Master Examples	71
Single Master and Multiple Nodes	71
Single Master, Multiple etcd, and Multiple Nodes	72
2.6.4.2. Multiple Masters Examples	73
Multiple Masters with Multiple etcd	74
Multiple Masters with Master and etcd on the Same Host	76
2.6.5. Running the Advanced Installation	78

2.6.5.1. Running the RPM-based Installer	78
2.6.5.2. Running the Containerized Installer	78
2.6.6. Verifying the Installation	79
Verifying Multiple etcd Hosts	80
Verifying Multiple Masters Using HAProxy	80
2.6.7. Uninstalling OpenShift Container Platform	80
2.6.7.1. Uninstalling Nodes	81
2.6.8. Known Issues	82
2.6.9. What's Next?	82
2.7. DISCONNECTED INSTALLATION	82
2.7.1. Overview	82
2.7.2. Prerequisites	83
2.7.3. Required Software and Components	83
2.7.3.1. Syncing Repositories	83
2.7.3.2. Syncing Images	84
2.7.3.3. Preparing Images for Export	86
2.7.4. Repository Server	87
2.7.4.1. Placing the Software	88
2.7.5. OpenShift Container Platform Systems	88
2.7.5.1. Building Your Hosts	88
2.7.5.2. Connecting the Repositories	88
2.7.5.3. Host Preparation	89
2.7.6. Installing OpenShift Container Platform	89
2.7.6.1. Importing OpenShift Container Platform Containerized Components	89
2.7.6.2. Running the OpenShift Container Platform Installer	90
2.7.6.3. Creating the Internal Docker Registry	90
2.7.7. Post-Installation Changes	90
2.7.7.1. Re-tagging S2I Builder Images	90
2.7.7.2. Configuring a Registry Location	90
2.7.7.3. Creating an Administrative User	91
2.7.7.4. Modifying the Security Policies	92
2.7.7.5. Editing the Image Stream Definitions	92
2.7.7.6. Loading the Container Images	93
2.7.8. Installing a Router	94
2.8. INSTALLING A STAND-ALONE DEPLOYMENT OF OPENSHIFT CONTAINER REGISTRY	94
2.8.1. About OpenShift Container Registry	94
2.8.2. Minimum Hardware Requirements	94
2.8.3. Supported System Topologies	95
2.8.4. Host Preparation	95
2.8.5. Installation Methods	95
2.8.5.1. Quick Installation for Stand-alone OpenShift Container Registry	96
2.8.5.2. Advanced Installation for Stand-alone OpenShift Container Registry	96
CHAPTER 3. SETTING UP THE REGISTRY	100
3.1. REGISTRY OVERVIEW	100
3.1.1. About the Registry	100
3.1.2. Integrated or Stand-alone Registries	100
3.2. DEPLOYING A REGISTRY ON EXISTING CLUSTERS	100
3.2.1. Overview	100
3.2.2. Deploying the Registry	100
3.2.3. Deploying the Registry 3.2.3. Deploying the Registry as a DaemonSet	100
3.2.4. Registry Compute Resources	101
3.2.5. Storage for the Registry	101

3.2.5.1. Production Use	102
3.2.5.1.1. Use Amazon S3 as a Storage Back-end	102
3.2.5.2. Non-Production Use	103
3.2.6. Enabling the Registry Console	103
3.2.6.1. Deploying the Registry Console	104
3.2.6.2. Securing the Registry Console	104
3.2.6.3. Troubleshooting the Registry Console	105
3.2.6.3.1. Debug Mode	105
3.2.6.3.2. Display SSL Certificate Path	105
3.3. ACCESSING THE REGISTRY	106
3.3.1. Viewing Logs	106
3.3.2. File Storage	106
3.3.3. Accessing the Registry Directly	108
3.3.3.1. User Prerequisites	108
3.3.3.2. Logging in to the Registry	109
3.3.3.3. Pushing and Pulling Images	109
3.4. SECURING AND EXPOSING THE REGISTRY	110
3.4.1. Securing the Registry	110
3.4.2. Exposing the Registry	113
3.4.2.1. Exposing a Secure Registry	115
3.4.2.2. Exposing a Non-Secure Registry	116
3.5. EXTENDED REGISTRY CONFIGURATION	117
3.5.1. Maintaining the Registry IP Address	117
3.5.2. Whitelisting Docker Registries	118
3.5.3. Overriding the Registry Configuration	118
3.5.4. Registry Configuration Reference	120
3.5.4.1. Log	121
3.5.4.2. Hooks	121
3.5.4.3. Storage	121
3.5.4.4. Auth	122
3.5.4.5. Middleware	122
3.5.4.5.1. CloudFront Middleware	123
3.5.4.5.2. Overriding Middleware Configuration Options	124
3.5.4.5.3. Image Pullthrough	125
3.5.4.5.4. Manifest Schema v2 Support	125
	126
3.5.4.6. Reporting 3.5.4.7. HTTP	126
3.5.4.8. Notifications	126
3.5.4.9. Redis	126
3.5.4.10. Health	126
3.5.4.11. Proxy	127
3.6. KNOWN ISSUES	127
3.6.1. Overview	127
3.6.2. Image Push Errors with Scaled Registry Using Shared NFS Volume	127
3.6.3. Pull of Internally Managed Image Fails with "not found" Error	127
3.6.4. Image Push Fails with "500 Internal Server Error" on S3 Storage	128
3.6.5. Image Pruning Fails	128
CHAPTER 4. SETTING UP A ROUTER	130
4.1. ROUTER OVERVIEW	130
4.1.1. About Routers	130
4.1.2. Router Service Account	130
4.1.2.1. Permission to Access Labels	130

	4.2. USING THE DEFAULT HAPROXY ROUTER	131
	4.2.1. Overview	131
	4.2.2. Creating a Router	132
	4.2.3. Other Basic Router Commands	132
	4.2.4. Filtering Routes to Specific Routers	133
	4.2.5. Highly-Available Routers	134
	4.2.6. Customizing the Router Service Ports	134
	4.2.7. Working With Multiple Routers	134
	4.2.8. Adding a Node Selector to a Deployment Configuration	134
	4.2.9. Using Router Shards	135
	4.2.9.1. Creating Router Shards	137
	4.2.9.2. Modifying Router Shards	139
	4.2.9.3. Using Namespace Router Shards	140
	4.2.10. Finding the Host Name of the Router	141
	4.2.11. Customizing the Default Routing Subdomain	142
	4.2.12. Forcing Route Host Names to a Custom Routing Subdomain	142
	4.2.13. Using Wildcard Certificates	143
	4.2.14. Manually Redeploy Certificates	143
	4.2.15. Using Secured Routes	144
	4.2.16. Using Wildcard Routes (for a Subdomain)	145
	4.2.17. Using the Container Network Stack	151
	4.2.18. Exposing Router Metrics	151
	4.2.19. Preventing Connection Failures During Restarts	153
	4.2.20. ARP Cache Tuning for Large-scale Clusters	153
	4.2.21. Protecting Against DDoS Attacks	154
	4.3. DEPLOYING A CUSTOMIZED HAPROXY ROUTER	155
	4.3.1. Overview	155
	4.3.2. Obtaining the Router Configuration Template	156
	4.3.3. Modifying the Router Configuration Template	156
	4.3.3.1. Background	156
	4.3.3.2. Go Template Actions	156
	4.3.3.3. Router Provided Information	157
	4.3.3.4. Annotations	162
	4.3.3.5. Environment Variables	162
	4.3.3.6. Example Usage	163
	4.3.4. Using a ConfigMap to Replace the Router Configuration Template	164
	4.3.5. Using Stick Tables	166
	4.3.6. Rebuilding Your Router	167
	4.4. CONFIGURING THE HAPROXY ROUTER TO USE THE PROXY PROTOCOL	168
	4.4.1. Overview	168
	4.4.2. Why Use the PROXY Protocol?	168
	4.4.3. Using the PROXY Protocol	168
	4.5. USING THE F5 ROUTER PLUG-IN	172
	4.5.1. Overview	172
	4.5.2. Prerequisites and Supportability	173
	4.5.2.1. Configuring the Virtual Servers	173
	4.5.3. Deploying the F5 Router	174
	4.5.4. F5 Router Partition Paths	175
	4.5.5. Setting Up F5 Native Integration	175
(CHAPTER 5. UPGRADING A CLUSTER	178
١	5.1. OVERVIEW	178
	5.1.1. In-place or Blue-Green Upgrades	178

In-place Upgrades	178
Blue-green Deployments	178
5.2. PERFORMING AUTOMATED IN-PLACE CLUSTER UPGRADES	178
5.2.1. Overview	178
5.2.2. Preparing for an Automated Upgrade	179
5.2.3. Using the Installer to Upgrade	180
5.2.4. Running Upgrade Playbooks Directly	18
5.2.4.1. Upgrading the Control Plane and Nodes in Separate Phases	181
5.2.4.2. Customizing Node Upgrades	182
5.2.4.3. Customizing Upgrades With Ansible Hooks	182
5.2.4.3.1. Limitations	183
5.2.4.3.2. Using Hooks	183
5.2.4.3.3. Available Upgrade Hooks	183
5.2.4.4. Upgrading to the Latest OpenShift Container Platform 3.5 Release	184
5.2.5. Upgrading the EFK Logging Stack	185
5.2.6. Upgrading Cluster Metrics	186
5.2.7. Verifying the Upgrade	186
5.3. PERFORMING MANUAL IN-PLACE CLUSTER UPGRADES	188
5.3.1. Overview	188
5.3.2. Preparing for a Manual Upgrade	188
5.3.3. Upgrading Master Components	190
5.3.4. Updating Policy Definitions	192
5.3.5. Upgrading Nodes	194
5.3.6. Upgrading the Router	196
5.3.7. Upgrading the Registry	196
5.3.8. Updating the Default Image Streams and Templates	197
5.3.9. Importing the Latest Images	199
5.3.10. Upgrading the EFK Logging Stack	200
5.3.11. Upgrading Cluster Metrics	201
5.3.12. Additional Manual Steps Per Release	201
5.3.12.1. OpenShift Container Platform 3.5.5.5	202
Migrating PetSets to StatefulSets	202
Migrating Jobs	202
5.3.12.2. OpenShift Container Platform 3.5.5.8	202
5.3.12.3. OpenShift Container Platform 3.5.5.24	202
5.3.12.4. OpenShift Container Platform 3.5.5.26	202
5.3.12.5. OpenShift Container Platform 3.5.5.31	203
5.3.13. Verifying the Upgrade	203
5.4. BLUE-GREEN DEPLOYMENTS	204
5.4.1. Overview	204
5.4.2. Preparing for a Blue-Green Upgrade	205
5.4.2.1. Sharing Software Entitlements	205
5.4.2.2. Labeling Blue Nodes	206
5.4.2.3. Creating and Labeling Green Nodes	206
5.4.2.4. Verifying Green Nodes	207
5.4.3. Registry and Router Canary Deployments	208
5.4.4. Warming the Green Nodes	208
5.4.5. Evacuating and Decommissioning Blue Nodes	209
5.5. OPERATING SYSTEM UPDATES AND UPGRADES	210
5.5.1. Updating and Upgrading the Operating System	210
CHAPTER 6. DOWNGRADING OPENSHIFT	212
6.1. OVERVIEW	212

	6.2. VERIFYING BACKUPS	212
	6.3. SHUTTING DOWN THE CLUSTER	212
	6.4. REMOVING RPMS	213
	6.5. DOWNGRADING DOCKER	213
	6.6. REINSTALLING RPMS	213
	6.7. RESTORING ETCD	214
	6.8. BRINGING OPENSHIFT CONTAINER PLATFORM SERVICES BACK ONLINE	214
	6.9. VERIFYING THE DOWNGRADE	214

12.1. OVERVIEW	258
12.2. CONFIGURING IDENTITY PROVIDERS WITH ANSIBLE	258
12.3. IDENTITY PROVIDERS	259
12.3.1. Mapping Identities to Users	260
12.3.2. Allow All	261
12.3.3. Deny All	261
12.3.4. HTPasswd	262
12.3.5. Keystone	264
12.3.6. LDAP Authentication	264
12.3.7. Basic Authentication (Remote)	267
12.3.8. Request Header	268
12.3.9. GitHub	276
12.3.10. GitLab	277
12.3.11. Google	278
12.3.12. OpenID Connect	279
12.4. TOKEN OPTIONS	282
12.5. GRANT OPTIONS	283
12.6. SESSION OPTIONS	283
12.7. PREVENTING CLI VERSION MISMATCH WITH USER AGENT	284
CHAPTER 13. SYNCING GROUPS WITH LDAP	287
13.1. OVERVIEW	287
13.2. CONFIGURING LDAP SYNC	287

13.2.1. LDAP Client Configuration	287
13.2.2. LDAP Query Definition	288
13.2.3. User-Defined Name Mapping	289
13.3. RUNNING LDAP SYNC	289
13.4. RUNNING A GROUP PRUNING JOB	290
13.5. SYNC EXAMPLES	290
13.5.1. RFC 2307	291
13.5.1.1. RFC2307 with User-Defined Name Mappings	293
13.5.2. RFC 2307 with User-Defined Error Tolerances	295
13.5.3. Active Directory	297
13.5.4. Augmented Active Directory	299
13.6. NESTED MEMBERSHIP SYNC EXAMPLE	302
13.7. LDAP SYNC CONFIGURATION SPECIFICATION	305
13.7.1. v1.LDAPSyncConfig	305
13.7.2. v1.StringSource	307
13.7.3. v1.LDAPQuery	308
13.7.4. v1.RFC2307Config	309
13.7.5. v1.ActiveDirectoryConfig	310

CHAPTER 14. ADVANCED LDAP CONFIGURATION	312
14.1. OVERVIEW	312
14.2. SETTING UP SSSD FOR LDAP FAILOVER	312
14.2.1. Overview	312
14.2.2. Prerequisites for Authenticating Proxy Setup	312
14.2.3. Phase 1: Certificate Generation	313
14.2.4. Phase 2: Authenticating Proxy Setup	314
14.2.4.1. Step 1: Copy Certificates	314
14.2.4.2. Step 2: SSSD Configuration	314
14.2.4.3. Step 3: Apache Configuration	315
14.2.5. Phase 3: OpenShift Container Platform Configuration	317
14.3. CONFIGURING FORM-BASED AUTHENTICATION	318
14.3.1. Overview	318
14.3.2. Prepare a Login Page	318
14.3.3. Install Another Apache Module	318
14.3.4. Apache Configuration	319
14.3.5. OpenShift Container Platform Configuration	319
14.4. CONFIGURING EXTENDED LDAP ATTRIBUTES	320
14.4.1. Overview	320
14.4.2. Prerequisites	320
14.4.3. Configuring SSSD	320
14.4.4. Configuring Apache	320
14.4.5. Configuring OpenShift Container Platform	321
14.4.6. Debugging Notes	322
CHAPTER 15. CONFIGURING THE SDN	323
15.1. OVERVIEW	323
15.2. CONFIGURING THE POD NETWORK WITH ANSIBLE	323
15.3. CONFIGURING THE POD NETWORK ON MASTERS	324
15.4. CONFIGURING THE POD NETWORK ON NODES	324
15.5. MIGRATING BETWEEN SDN PLUG-INS	325
15.6. EXTERNAL ACCESS TO THE CLUSTER NETWORK	325
15.7. USING FLANNEL	325

CHAPTER 16. CONFIGURING NUAGE SDN 16.1. NUAGE SDN AND OPENSHIFT CONTAINER PLATFORM	327 327
16.2. DEVELOPER WORKFLOW	327
16.3. OPERATIONS WORKFLOW	327
16.4. INSTALLATION	327
16.4.1. Installation for a Single Master	327
16.4.2. Installation for Multiple Masters (HA)	328
CHAPTER 17. CONFIGURING FOR AWS	330
17.1. OVERVIEW	330
17.2. CONFIGURING AWS VARIABLES	330
17.3. CONFIGURING OPENSHIFT CONTAINER PLATFORM MASTERS FOR AWS	330
17.3.1. Configuring OpenShift Container Platform for AWS with Ansible	330
17.3.2. Manually Configuring OpenShift Container Platform Masters for AWS	331
17.3.3. Manually Configuring OpenShift Container Platform Nodes for AWS	331
17.4. SETTING KEY VALUE ACCESS PAIRS	332
17.5. APPLYING CONFIGURATION CHANGES	332
CHAPTER 18. CONFIGURING FOR OPENSTACK	333
18.1. OVERVIEW	333
18.2. CONFIGURING OPENSTACK VARIABLES	333
18.3. CONFIGURING OPENSHIFT CONTAINER PLATFORM MASTERS FOR OPENSTACK	333
18.3.1. Configuring OpenShift Container Platform for OpenStack with Ansible	333
18.3.2. Manually Configuring OpenShift Container Platform Masters for OpenStack	334
18.3.3. Manually Configuring OpenShift Container Platform Nodes for OpenStack	335
CHAPTER 19. CONFIGURING FOR GCE	336
19.1. OVERVIEW	336
19.2. CONFIGURING MASTERS	336
19.2.1. Configuring OpenShift Container Platform Masters for GCE with Ansible	336
19.2.2. Manually Configuring OpenShift Container Platform Masters for GCE	336
19.3. CONFIGURING NODES	337
19.4. CONFIGURING MULTIZONE SUPPORT IN A GCE DEPLOYMENT	337
CHAPTER 20. CONFIGURING FOR AZURE	339
20.1. OVERVIEW	339
20.2. THE AZURE CONFIGURATION FILE	339
20.3. CONFIGURING MASTERS	339
20.4. CONFIGURING NODES	340
CHAPTER 21. CONFIGURING PERSISTENT STORAGE	341
21.1. OVERVIEW	341
21.2. PERSISTENT STORAGE USING NFS	341
21.2.1. Overview	341
21.2.2. Provisioning	341
21.2.3. Enforcing Disk Quotas	343
21.2.4. NFS Volume Security	343
21.2.4.1. Group IDs	344
21.2.4.2. User IDs	345
21.2.4.3. SELinux	346
21.2.4.4. Export Settings	346
21.2.5. Reclaiming Resources	347
21.2.6. Automation	347
21.2.7. Additional Configuration and Troubleshooting	347

21.3. PERSISTENT STORAGE USING GLUSTERFS	348
21.3.1. Overview	348
21.3.1.1. Containerized Red Hat Gluster Storage	348
21.3.1.2. Container Native Storage Recommendations	348
21.3.1.2.1. Creation Time of Volumes with Container Native Storage	349
21.3.1.2.2. Deletion Time of Volumes with Container Native Storage	349
21.3.1.2.3. Recommended Memory Requirements for Container Native Storage	349
21.3.1.3. Dedicated Storage Cluster	349
21.3.2. Support Requirements	350
21.3.2.1. Supported Operating Systems	351
21.3.2.2. Environment Requirements	351
21.3.3. Provisioning	351
21.3.3.1. Creating Gluster Endpoints	352
21.3.3.2. Creating the Persistent Volume	353
21.3.3.3. Creating the Persistent Volume Claim	354
21.3.4. Gluster Volume Security	355
21.3.4.1. Group IDs	355
21.3.4.2. User IDs	356
21.3.4.3. SELinux	357
21.4. PERSISTENT STORAGE USING OPENSTACK CINDER	357
21.4.1. Overview	357
21.4.2. Provisioning	358
21.4.2.1. Creating the Persistent Volume	358
21.4.2.2. Volume Format	359
21.5. PERSISTENT STORAGE USING CEPH RADOS BLOCK DEVICE (RBD)	359
21.5.1. Overview	359
21.5.2. Provisioning	360
21.5.2.1. Creating the Ceph Secret	360
21.5.2.2. Creating the Persistent Volume	361
21.5.3. Ceph Volume Security	363
21.6. PERSISTENT STORAGE USING AWS ELASTIC BLOCK STORE	363
21.6.1. Overview	363
21.6.2. Provisioning	364
21.6.2.1. Creating the Persistent Volume	364
21.6.2.2. Volume Format	365
21.7. PERSISTENT STORAGE USING GCE PERSISTENT DISK	365
21.7.1. Overview	365
21.7.2. Provisioning	366
21.7.2.1. Creating the Persistent Volume	366
21.7.2.2. Volume Format	367
21.7.2.3. Multi-zone Configuration	367
21.8. PERSISTENT STORAGE USING ISCSI	368
21.8.1. Overview	368
21.8.2. Provisioning	368
21.8.2.1. Enforcing Disk Quotas	369
21.8.2.2. iSCSI Volume Security	369
21.9. PERSISTENT STORAGE USING FIBRE CHANNEL	369
21.9.1. Overview	369
21.9.2. Provisioning	370
21.9.2.1. Enforcing Disk Quotas	370
21.9.2.2. Fibre Channel Volume Security	371
21.10. PERSISTENT STORAGE USING AZURE DISK	371
21.10.1. Overview	371

	21.10.2. Prerequisites	371
	21.10.3. Provisioning	371
	21.10.3.1. Creating the Persistent Volume	371
	21.10.3.2. Volume Format	373
	21.11. PERSISTENT STORAGE USING AZURE FILE	373
	21.11.1. Overview	373
	21.11.2. Before you begin	373
	21.11.3. Creating the Persistent Volume	374
	21.11.4. Creating the Azure Storage Account Secret	374
	21.12. DYNAMIC PROVISIONING AND CREATING STORAGE CLASSES	375
	21.12.1. Overview	375

CHAPTER 1. OVERVIEW

OpenShift Container Platform Installation and Configuration topics cover the basics of installing and configuring OpenShift Container Platform in your environment. Configuration, management, and logging are also covered. Use these topics for the one-time tasks required to quickly set up your OpenShift Container Platform environment and configure it based on your organizational needs.

For day to day cluster administration tasks, see Cluster Administration.

CHAPTER 2. INSTALLING A CLUSTER

2.1. PLANNING

2.1.1. Initial Planning

For production environments, several factors influence installation. Consider the following questions as you read through the documentation:

- Which installation method do you want to use? The Installation Methods section provides some information about the quick and advanced installation methods.
- How many hosts do you require in the cluster? The Environment Scenarios section provides multiple examples of Single Master and Multiple Master configurations.
- How many pods are required in your cluster? The Sizing Considerations section provides limits for nodes and pods so you can calculate how large your environment needs to be.
- Is high availability required? High availability is recommended for fault tolerance. In this
 situation, you might aim to use the Multiple Masters Using Native HA example as a basis for
 your environment.
- Which installation type do you want to use: RPM or containerized? Both installations provide a
 working OpenShift Container Platform environment, but you might have a preference for a
 particular method of installing, managing, and updating your services.
- Is my installation supported if integrating with other technologies? See the OpenShift Container Platform Tested Integrations for a list of tested integrations.

2.1.2. Installation Methods

Both the quick and advanced installation methods are supported for development and production environments. If you want to quickly get OpenShift Container Platform up and running to try out for the first time, use the quick installer and let the interactive CLI guide you through the configuration options relevant to your environment.

For the most control over your cluster's configuration, you can use the advanced installation method. This method is particularly suited if you are already familiar with Ansible. However, following along with the OpenShift Container Platform documentation should equip you with enough information to reliably deploy your cluster and continue to manage its configuration post-deployment using the provided Ansible playbooks directly.

If you install initially using the quick installer, you can always further tweak your cluster's configuration and adjust the number of hosts in the cluster using the same installer tool. If you wanted to later switch to using the advanced method, you can create an inventory file for your configuration and carry on that way.

2.1.3. Sizing Considerations

Determine how many nodes and pods you require for your OpenShift Container Platform cluster. Cluster scalability correlates to the number of pods in a cluster environment. That number influences the other numbers in your setup.

The following table provides the maximum sizing limits for nodes and pods:

Туре	Maximum
Maximum nodes per cluster	1000
Maximum pods per cluster	120,000
Maximum pods per node	250
Maximum pods per core	10

IMPORTANT

Oversubscribing the physical resources on a node affects resource guarantees the Kubernetes scheduler makes during pod placement. Learn what measures you can take to avoid memory swapping.

Determine how many pods are expected to fit per node:

Maximum Pods per Cluster / Expected Pods per Node = Total Number of Nodes

Example Scenario

If you want to scope your cluster for 2200 pods per cluster, you would need at least 9 nodes, assuming that there are 250 maximum pods per node:

If you increase the number of nodes to 20, then the pod distribution changes to 110 pods per node:

2.1.4. Environment Scenarios

This section outlines different examples of scenarios for your OpenShift Container Platform environment. Use these scenarios as a basis for planning your own OpenShift Container Platform cluster.

NOTE

Moving from a single master cluster to multiple masters after installation is not supported.

2.1.4.1. Single Master and Multiple Nodes

The following table describes an example environment for a single master (with embedded etcd) and two nodes:

Host Name	Infrastructure Component to Install
master.example.com	Master and node
node1.example.com	Node
node2.example.com	Node

2.1.4.2. Single Master, Multiple etcd, and Multiple Nodes

The following table describes an example environment for a single master, three **etcd** hosts, and two nodes:

Host Name	Infrastructure Component to Install
master.example.com	Master and node
etcd1.example.com	
etcd2.example.com	etcd
etcd3.example.com	
node1.example.com	Node
node2.example.com	Noue

NOTE

When specifying multiple **etcd** hosts, external **etcd** is installed and configured. Clustering of OpenShift Container Platform's embedded **etcd** is not supported.

2.1.4.3. Multiple Masters Using Native HA

The following describes an example environment for three masters, one HAProxy load balancer, three etcd hosts, and two nodes using the native HA method:

Host Name	Infrastructure Component to Install
master1.example.com	
master2.example.com	Master (clustered using native HA) and node
master3.example.com	
lb.example.com	HAProxy to load balance API master endpoints

Host Name	Infrastructure Component to Install
etcd1.example.com	
etcd2.example.com	etcd
etcd3.example.com	
node1.example.com	Node
node2.example.com	

NOTE

When specifying multiple **etcd** hosts, external **etcd** is installed and configured. Clustering of OpenShift Container Platform's embedded **etcd** is not supported.

2.1.4.4. Stand-alone Registry

You can also install OpenShift Container Platform to act as a stand-alone registry using the OpenShift Container Platform's integrated registry. See <u>Installing a Stand-alone Registry</u> for details on this scenario.

2.1.5. RPM vs Containerized

An RPM installation installs all services through package management and configures services to run within the same user space, while a containerized installation installs services using container images and runs separate services in individual containers.

See the Installing on Containerized Hosts topic for more details on configuring your installation to use containerized services.

2.2. PREREQUISITES

2.2.1. System Requirements

The following sections identify the hardware specifications and system-level requirements of all hosts within your OpenShift Container Platform environment.

2.2.1.1. Red Hat Subscriptions

You must have an active OpenShift Container Platform subscription on your Red Hat account to proceed. If you do not, contact your sales representative for more information.

IMPORTANT

OpenShift Container Platform 3.5 requires Docker 1.12.

2.2.1.2. Minimum Hardware Requirements

The system requirements vary per host type:

Masters	 Physical or virtual system, or an instance running on a public or private laaS. Base OS: RHEL 7.3 with the "Minimal" installation option and the latest packages from the Extras channel, or RHEL Atomic Host 7.3.2 or later. RHEL 7.2 is also supported using Docker 1.12 and its dependencies. 2 vCPU. Minimum 16 GB RAM. Minimum 40 GB hard disk space for the file system containing /var/.
Nodes	 Physical or virtual system, or an instance running on a public or private laaS. Base OS: RHEL 7.3 or later with "Minimal" installation option, or RHEL Atomic Host 7.3.2 or later. RHEL 7.2 is also supported using Docker 1.12 and its dependencies. NetworkManager 1.0 or later. 1 vCPU. Minimum 8 GB RAM. Minimum 15 GB hard disk space for the file system containing /var/. An additional minimum 15 GB unallocated space to be used for Docker's storage back end; see Configuring Docker Storage.
External etcd Nodes	 Minimum 20 GB hard disk space for etcd data. Consult Hardware Recommendations to properly size your etcd nodes. Currently, OpenShift Container Platform stores image, build, and deployment metadata in etcd. You must periodically prune old resources. If you are planning to leverage a large number of images/builds/deployments, place etcd on machines with large amounts of memory and fast SSD drives.

IMPORTANT

OpenShift Container Platform only supports servers with the x86_64 architecture.

NOTE

Meeting the /var/file system sizing requirements in RHEL Atomic Host requires making changes to the default configuration. See Managing Storage in Red Hat Enterprise Linux Atomic Host for instructions on configuring this during or after installation.

2.2.1.3. Production Level Hardware Requirements

Test or sample environments function with the minimum requirements. For production environments, the following recommendations apply:

Master Hosts

In a highly available OpenShift Container Platform cluster with external etcd, a master host should have, in addition to the minimum requirements in the table above, 1 CPU core and 1.5 GB of memory for each 1000 pods. Therefore, the recommended size of a master host in an OpenShift Container Platform cluster of 2000 pods would be the minimum requirements of 2 CPU cores and 16 GB of RAM, plus 2 CPU cores and 3 GB of RAM, totaling 4 CPU cores and 19 GB of RAM.

When planning an environment with multiple masters, a minimum of three etcd hosts and a load-balancer between the master hosts are required.

The OpenShift Container Platform master caches describilized versions of resources aggressively to ease CPU load. However, in smaller clusters of less than 1000 pods, this cache can waste a lot of memory for negligible CPU load reduction. The default cache size is 50,000 entries, which, depending on the size of your resources, can grow to occupy 1 to 2 GB of memory. This cache size can be reduced using the following setting the in /etc/origin/master/master-config.yaml:

```
kubernetesMasterConfig:
   apiServerArguments:
    deserialization-cache-size:
       - "1000"
```

Node Hosts

The size of a node host depends on the expected size of its workload. As an OpenShift Container Platform cluster administrator, you will need to calculate the expected workload, then add about 10 percent for overhead. For production environments, allocate enough resources so that a node host failure does not affect your maximum capacity.

Use the above with the following table to plan the maximum loads for nodes and pods:

Host	Sizing Recommendation
Maximum nodes per cluster	1000
Maximum pods per cluster	120000
Maximum pods per nodes	250
Maximum pods per core	10

IMPORTANT

Oversubscribing the physical resources on a node affects resource guarantees the Kubernetes scheduler makes during pod placement. Learn what measures you can take to avoid memory swapping.

2.2.1.4. Configuring Core Usage

By default, OpenShift Container Platform masters and nodes use all available cores in the system they run on. You can choose the number of cores you want OpenShift Container Platform to use by setting the **GOMAXPROCS** environment variable.

For example, run the following before starting the server to make OpenShift Container Platform only run on one core:

```
# export GOMAXPROCS=1
```

2.2.1.5. SELinux

Security-Enhanced Linux (SELinux) must be enabled on all of the servers before installing OpenShift Container Platform or the installer will fail. Also, configure SELINUXTYPE=targeted in the /etc/selinux/config file:

```
# This file controls the state of SELinux on the system.
# SELINUX= can take one of these three values:
# enforcing - SELinux security policy is enforced.
# permissive - SELinux prints warnings instead of enforcing.
# disabled - No SELinux policy is loaded.
SELINUX=enforcing
# SELINUXTYPE= can take one of these three values:
# targeted - Targeted processes are protected,
# minimum - Modification of targeted policy. Only selected processes are protected.
# mls - Multi Level Security protection.
SELINUXTYPE=targeted
```

2.2.1.6. NTP

You must enable Network Time Protocol (NTP) to prevent masters and nodes in the cluster from going out of sync. Set openshift_clock_enabled to true in the Ansible playbook to enable NTP on masters and nodes in the cluster during Ansible installation.

```
# openshift_clock_enabled=true
```

2.2.1.7. Security Warning

OpenShift Container Platform runs containers on your hosts, and in some cases, such as build operations and the registry service, it does so using privileged containers. Furthermore, those containers access your host's Docker daemon and perform docker build and docker push operations. As such, you should be aware of the inherent security risks associated with performing docker run operations on arbitrary images as they effectively have root access.

For more information, see these articles:

- http://opensource.com/business/14/7/docker-security-selinux
- https://docs.docker.com/engine/security/security/

To address these risks, OpenShift Container Platform uses security context constraints that control the actions that pods can perform and what it has the ability to access.

2.2.2. Environment Requirements

The following section defines the requirements of the environment containing your OpenShift Container Platform configuration. This includes networking considerations and access to external services, such as Git repository access, storage, and cloud infrastructure providers.

2.2.2.1. DNS

OpenShift Container Platform requires a fully functional DNS server in the environment. This is ideally a separate host running DNS software and can provide name resolution to hosts and containers running on the platform.

IMPORTANT

Adding entries into the /etc/hosts file on each host is not enough. This file is not copied into containers running on the platform.

Key components of OpenShift Container Platform run themselves inside of containers and use the following process for name resolution:

- 1. By default, containers receive their DNS configuration file (/etc/resolv.conf) from their host.
- OpenShift Container Platform then inserts one DNS value into the pods (above the node's
 nameserver values). That value is defined in the /etc/origin/node/node-config.yaml file by the
 dnsIP parameter, which by default is set to the address of the host node because the host is
 using dnsmasq.
- 3. If the dnsIP parameter is omitted from the *node-config.yaml* file, then the value defaults to the kubernetes service IP, which is the first nameserver in the pod's /etc/resolv.conf file.

As of OpenShift Container Platform 3.2, **dnsmasq** is automatically configured on all masters and nodes. The pods use the nodes as their DNS, and the nodes forward the requests. By default, **dnsmasq** is configured on the nodes to listen on port 53, therefore the nodes cannot run any other type of DNS application.

NOTE

NetworkManager is required on the nodes in order to populate **dnsmasq** with the DNS IP addresses.

The following is an example set of DNS records for the Single Master and Multiple Nodes scenario:

master A 10.64.33.100 node1 A 10.64.33.101 node2 A 10.64.33.102

If you do not have a properly functioning DNS environment, you could experience failure with:

- Product installation via the reference Ansible-based scripts
- Deployment of the infrastructure containers (registry, routers)
- Access to the OpenShift Container Platform web console, because it is not accessible via IP address alone

2.2.2.1.1. Configuring Hosts to Use DNS

Make sure each host in your environment is configured to resolve hostnames from your DNS server. The configuration for hosts' DNS resolution depend on whether DHCP is enabled. If DHCP is:

- Disabled, then configure your network interface to be static, and add DNS nameservers to NetworkManager.
- Enabled, then the NetworkManager dispatch script automatically configures DNS based on the DHCP configuration. Optionally, you can add a value to dnsIP in the node-config.yaml file to prepend the pod's resolv.conf file. The second nameserver is then defined by the host's first nameserver. By default, this will be the IP address of the node host.

NOTE

For most configurations, do not set the **openshift_dns_ip** option during the advanced installation of OpenShift Container Platform (using Ansible), because this option overrides the default IP address set by **dnsIP**.

Instead, allow the installer to configure each node to use <code>dnsmasq</code> and forward requests to SkyDNS or the external DNS provider. If you do set the <code>openshift_dns_ip</code> option, then it should be set either with a DNS IP that queries SkyDNS first, or to the SkyDNS service or endpoint IP (the Kubernetes service IP).

To verify that hosts can be resolved by your DNS server:

1. Check the contents of /etc/resolv.conf:

```
$ cat /etc/resolv.conf
# Generated by NetworkManager
search example.com
nameserver 10.64.33.1
# nameserver updated by /etc/NetworkManager/dispatcher.d/99-origin-
dns.sh
```

In this example, 10.64.33.1 is the address of our DNS server.

2. Test that the DNS servers listed in /etc/resolv.conf are able to resolve host names to the IP addresses of all masters and nodes in your OpenShift Container Platform environment:

```
$ dig <node_hostname> @<IP_address> +short
```

For example:

```
$ dig master.example.com @10.64.33.1 +short
10.64.33.100
$ dig node1.example.com @10.64.33.1 +short
10.64.33.101
```

2.2.2.1.2. Disabling dnsmasq

If you want to disable **dnsmasq** (for example, if your **/etc/resolv.conf** is managed by a configuration tool other than NetworkManager), then set **openshift_use_dnsmasq** to **false** in the Ansible playbook.

However, certain containers do not properly move to the next nameserver when the first issues **SERVFAIL**. Red Hat Enterprise Linux (RHEL)-based containers do not suffer from this, but certain versions of **uclibc** and **musl** do.

2.2.2.1.3. Configuring a DNS Wildcard

Optionally, configure a wildcard for the router to use, so that you do not need to update your DNS configuration when new routes are added.

A wildcard for a DNS zone must ultimately resolve to the IP address of the OpenShift Container Platform router.

For example, create a wildcard DNS entry for **cloudapps** that has a low time-to-live value (TTL) and points to the public IP address of the host where the router will be deployed:

*.cloudapps.example.com. 300 IN A 192.168.133.2

In almost all cases, when referencing VMs you must use host names, and the host names that you use must match the output of the **hostname** -f command on each node.

WARNING

In your /etc/resolv.conf file on each node host, ensure that the DNS server that has the wildcard entry is not listed as a nameserver or that the wildcard domain is not listed in the search list. Otherwise, containers managed by OpenShift Container Platform may fail to resolve host names properly.

2.2.2.2. Network Access

A shared network must exist between the master and node hosts. If you plan to configure multiple masters for high-availability using the advanced installation method, you must also select an IP to be configured as your virtual IP (VIP) during the installation process. The IP that you select must be routable between all of your nodes, and if you configure using a FQDN it should resolve on all nodes.

2.2.2.1. NetworkManager

NetworkManager, a program for providing detection and configuration for systems to automatically connect to the network, is required.

2.2.2.2. Required Ports

The OpenShift Container Platform installation automatically creates a set of internal firewall rules on each host using **iptables**. However, if your network configuration uses an external firewall, such as a hardware-based firewall, you must ensure infrastructure components can communicate with each other through specific ports that act as communication endpoints for certain processes or services.

Ensure the following ports required by OpenShift Container Platform are open on your network and configured to allow access between hosts. Some ports are optional depending on your configuration and usage.

Table 2.1. Node to Node

4789	UDP	Required for SDN communication between pods on separate hosts.	
------	-----	--	--

Table 2.2. Nodes to Master

53 or 8053	TCP/ UDP	Required for DNS resolution of cluster services (SkyDNS). Installations prior to 3.2 or environments upgraded to 3.2 use port 53. New installations will use 8053 by default so that dnsmasq may be configured.
4789	UDP	Required for SDN communication between pods on separate hosts.
443 or 8443	ТСР	Required for node hosts to communicate to the master API, for the node hosts to post back status, to receive tasks, and so on.

Table 2.3. Master to Node

4789	UDP	Required for SDN communication between pods on separate hosts.
10250	ТСР	The master proxies to node hosts via the Kubelet for oc commands.

NOTE

In the following table, **(L)** indicates the marked port is also used in *loopback mode*, enabling the master to communicate with itself.

In a single-master cluster:

- Ports marked with (L) must be open.
- Ports not marked with (L) need not be open.

In a multiple-master cluster, all the listed ports must be open.

Table 2.4. Master to Master

53 (L) or 8053 (L)	TCP/ UDP	Required for DNS resolution of cluster services (SkyDNS). Installations prior to 3.2 or environments upgraded to 3.2 use port 53. New installations will use 8053 by default so that dnsmasq may be configured.
2049 (L)	TCP/ UDP	Required when provisioning an NFS host as part of the installer.
2379	ТСР	Used for standalone etcd (clustered) to accept changes in state.
2380	ТСР	etcd requires this port be open between masters for leader election and peering connections when using standalone etcd (clustered).
4001 (L)	ТСР	Used for embedded etcd (non-clustered) to accept changes in state.

4789 (L)	UDP	Required for SDN communication between pods on separate hosts.	
----------	-----	--	--

Table 2.5. External to Load Balancer

9000 TCP If you choose the native HA method, optional to allow access to HAProxy statistics page.
--

Table 2.6. External to Master

443 or 8443 TCP Required for node hosts to communicate to the master A post back status, to receive tasks, and so on.	PI, for node hosts to
---	-----------------------

Table 2.7. laaS Deployments

22	ТСР	Required for SSH by the installer or system administrator.
53 or 8053	TCP/ UDP	Required for DNS resolution of cluster services (SkyDNS). Installations prior to 3.2 or environments upgraded to 3.2 use port 53. New installations will use 8053 by default so that dnsmasq may be configured. Only required to be internally open on master hosts.
80 or 443	ТСР	For HTTP/HTTPS use for the router. Required to be externally open on node hosts, especially on nodes running the router.
1936	TCP	For router statistics use. Required to be open when running the template router to access statistics, and can be open externally or internally to connections depending on if you want the statistics to be expressed publicly.
4001	ТСР	For embedded etcd (non-clustered) use. Only required to be internally open on the master host. 4001 is for server-client connections.
2379 and 2380	TCP	For standalone etcd use. Only required to be internally open on the master host. 2379 is for server-client connections. 2380 is for server-server connections, and is only required if you have clustered etcd.
4789	UDP	For VxLAN use (OpenShift SDN). Required only internally on node hosts.
8443	ТСР	For use by the OpenShift Container Platform web console, shared with the API server.
10250	ТСР	For use by the Kubelet. Required to be externally open on nodes.

Notes

- In the above examples, port 4789 is used for User Datagram Protocol (UDP).
- When deployments are using the SDN, the pod network is accessed via a service proxy, unless it is accessing the registry from the same node the registry is deployed on.

- OpenShift Container Platform internal DNS cannot be received over SDN. Depending on the
 detected values of openshift_facts, or if the openshift_ip and openshift_public_ip
 values are overridden, it will be the computed value of openshift_ip. For non-cloud
 deployments, this will default to the IP address associated with the default route on the master
 host. For cloud deployments, it will default to the IP address associated with the first internal
 interface as defined by the cloud metadata.
- The master host uses port 10250 to reach the nodes and does not go over SDN. It depends on the target host of the deployment and uses the computed values of openshift_hostname and openshift_public_hostname.

Table 2.8. Aggregated Logging

9200	ТСР	For Elasticsearch API use. Required to be internally open on any infrastructure nodes so Kibana is able to retrieve logs for display. It can be externally opened for direct access to Elasticsearch by means of a route. The route can be created using oc expose.
9300	TCP	For Elasticsearch inter-cluster use. Required to be internally open on any infrastructure node so the members of the Elasticsearch cluster may communicate with each other.

2.2.2.3. Persistent Storage

The Kubernetes persistent volume framework allows you to provision an OpenShift Container Platform cluster with persistent storage using networked storage available in your environment. This can be done after completing the initial OpenShift Container Platform installation depending on your application needs, giving users a way to request those resources without having any knowledge of the underlying infrastructure.

The Installation and Configuration Guide provides instructions for cluster administrators on provisioning an OpenShift Container Platform cluster with persistent storage using NFS, GlusterFS, Ceph RBD, OpenStack Cinder, AWS Elastic Block Store (EBS), GCE Persistent Disks, and iSCSI.

2.2.2.4. Cloud Provider Considerations

There are certain aspects to take into consideration if installing OpenShift Container Platform on a cloud provider.

2.2.2.4.1. Configuring a Security Group

When installing on AWS or OpenStack, ensure that you set up the appropriate security groups. These are some ports that you should have in your security groups, without which the installation will fail. You may need more depending on the cluster configuration you want to install. For more information and to adjust your security groups accordingly, see Required Ports for more information.

etcd Security Group	 tcp/2379 from masters tcp/2380 from etcd hosts
Master Security Group	 tcp/8443 from 0.0.0.0/0 tcp/53 from all OpenShift Container Platform hosts for environments installed prior to or upgraded to 3.2 udp/53 from all OpenShift Container Platform hosts for environments installed prior to or upgraded to 3.2 tcp/8053 from all OpenShift Container Platform hosts for new environments installed with 3.2 udp/8053 from all OpenShift Container Platform hosts for new environments installed with 3.2
Node Security Group	tcp/10250 from mastersudp/4789 from nodes
Infrastructure Nodes (ones that can host the OpenShift Container Platform router)	 tcp/443 from 0.0.0.0/0 tcp/80 from 0.0.0.0/0

If configuring ELBs for load balancing the masters and/or routers, you also need to configure Ingress and Egress security groups for the ELBs appropriately.

2.2.2.4.2. Overriding Detected IP Addresses and Host Names

Some deployments require that the user override the detected host names and IP addresses for the hosts. To see the default values, run the **openshift_facts** playbook:

ansible-playbook playbooks/byo/openshift_facts.yml

Now, verify the detected common settings. If they are not what you expect them to be, you can override them.

The Advanced Installation topic discusses the available Ansible variables in greater detail.

Variable	Usage
hostname	 Should resolve to the internal IP from the instances themselves. openshift_hostname overrides.

Variable	Usage
ip	 Should be the internal IP of the instance. openshift_ip will overrides.
public_hostname	 Should resolve to the external IP from hosts outside of the cloud. Provider openshift_public_hostname overrides.
public_ip	 Should be the externally accessible IP associated with the instance. openshift_public_ip overrides.
use_openshift_sdn	 Should be true unless the cloud is GCE. openshift_use_openshift_sdn overrides.

WARNING

If openshift_hostname is set to a value other than the metadata-provided private-dns-name value, the native cloud integration for those providers will no longer work.

In AWS, situations that require overriding the variables include:

Variable	Usage
hostname	The user is installing in a VPC that is not configured for both DNS hostnames and DNS resolution.
ip	Possibly if they have multiple network interfaces configured and they want to use one other than the default. You must first set openshift_set_node_ip to True . Otherwise, the SDN would attempt to use the hostname setting or try to resolve the host name for the IP.

Variable	Usage
public_hostname	 A master instance where the VPC subnet is not configured for Auto-assign Public IP. For external access to this master, you need to have an ELB or other load balancer configured that would provide the external access needed, or you need to connect over a VPN connection to the internal name of the host. A master instance where metadata is disabled. This value is not actually used by the nodes.
public_ip	 A master instance where the VPC subnet is not configured for Auto-assign Public IP. A master instance where metadata is disabled. This value is not actually used by the nodes.

If setting **openshift_hostname** to something other than the metadata-provided **private-dns-name** value, the native cloud integration for those providers will no longer work.

For EC2 hosts in particular, they must be deployed in a VPC that has both **DNS** host names and **DNS** resolution enabled, and openshift_hostname should not be overridden.

2.2.2.4.3. Post-Installation Configuration for Cloud Providers

Following the installation process, you can configure OpenShift Container Platform for AWS, OpenStack, or GCE.

2.3. HOST PREPARATION

2.3.1. Operating System Requirements

A base installation of RHEL 7.3 (with the latest packages from the Extras channel) or RHEL Atomic Host 7.3.2 or later is required for master and node hosts. RHEL 7.2 is also supported using Docker 1.12 and its dependencies. See the following documentation for the respective installation instructions, if required:

- Red Hat Enterprise Linux 7 Installation Guide
- Red Hat Enterprise Linux Atomic Host 7 Installation and Configuration Guide

2.3.2. Host Registration

Each host must be registered using Red Hat Subscription Manager (RHSM) and have an active OpenShift Container Platform subscription attached to access the required packages.

1. On each host, register with RHSM:

subscription-manager register --username=<user_name> --password=
<password>

2. List the available subscriptions:

```
# subscription-manager list --available --matches '*OpenShift*'
```

3. In the output for the previous command, find the pool ID for an OpenShift Container Platform subscription and attach it:

```
# subscription-manager attach --pool=<pool_id>
```

- 4. Disable all yum repositories:
 - a. Disable all the enabled RHSM repositories:

```
# subscription-manager repos --disable="*"
```

b. List the remaining yum repositories and note their names under repo id, if any:

```
# yum repolist
```

c. Use yum-config-manager to disable the remaining yum repositories:

```
# yum-config-manager --disable <repo_id>
```

Alternatively, disable all repositories:

```
yum-config-manager --disable \*
```

Note that this could take a few minutes if you have a large number of available repositories

5. Enable only the repositories required by OpenShift Container Platform 3.5:

```
# subscription-manager repos \
    --enable="rhel-7-server-rpms" \
    --enable="rhel-7-server-extras-rpms" \
    --enable="rhel-7-server-ose-3.5-rpms" \
    --enable="rhel-7-fast-datapath-rpms"
```

2.3.3. Installing Base Packages

For RHEL 7 systems:

1. Install the following base packages:

```
# yum install wget git net-tools bind-utils iptables-services
bridge-utils bash-completion kexec-tools sos psacct
```

2. Update the system to the latest packages:

```
# yum update
```

3. Install the following package, which provides OpenShift Container Platform utilities and pulls in other tools required by the quick and advanced installation methods, such as Ansible and related configuration files:

```
# yum install atomic-openshift-utils
```

4. Install the following *-excluder packages on each RHEL 7 system, which helps ensure your systems stay on the correct versions of atomic-openshift and docker packages when you are not trying to upgrade, according to the OpenShift Container Platform version:

```
\# yum install atomic-openshift-excluder atomic-openshift-docker-excluder
```

5. The *-excluder packages add entries to the exclude directive in the host's /etc/yum.conf file when installed. Run the following command on each host to remove the atomic-openshift packages from the list for the duration of the installation.

```
# atomic-openshift-excluder unexclude
```

For RHEL Atomic Host 7 systems:

1. Ensure the host is up to date by upgrading to the latest Atomic tree if one is available:

```
# atomic host upgrade
```

2. After the upgrade is completed and prepared for the next boot, reboot the host:

```
# systemctl reboot
```

2.3.4. Installing Docker

At this point, you should install Docker on all master and node hosts. This allows you to configure your Docker storage options before installing OpenShift Container Platform.

1. For RHEL 7 systems, install Docker 1.12.

NOTE

On RHEL Atomic Host 7 systems, Docker should already be installed, configured, and running by default.

The atomic-openshift-docker-excluder package that was installed in Installing Base Packages should ensure that the correct version of Docker is installed in this step:

```
# yum install docker
```

After the package installation is complete, verify that version 1.12 was installed:

```
# docker version
```

2. Edit the /etc/sysconfig/docker file and add --insecure-registry 172.30.0.0/16 to the OPTIONS parameter. For example:

OPTIONS='--selinux-enabled --insecure-registry 172.30.0.0/16'

If using the Quick Installation method, you can easily script a complete installation from a kickstart or cloud-init setup, change the default configuration file:

sed -i '/OPTIONS=.*/c\OPTIONS="--selinux-enabled --insecureregistry 172.30.0.0/16"' \
/etc/sysconfig/docker

NOTE

The Advanced Installation method automatically changes /etc/sysconfig/docker.

The --insecure-registry option instructs the Docker daemon to trust any Docker registry on the indicated subnet, rather than requiring a certificate.

IMPORTANT

172.30.0.0/16 is the default value of the servicesSubnet variable in the master-config.yaml file. If this has changed, then the --insecure-registry value in the above step should be adjusted to match, as it is indicating the subnet for the registry to use. Note that the openshift_portal_net variable can be set in the Ansible inventory file and used during the advanced installation method to modify the servicesSubnet variable.

NOTE

After the initial OpenShift Container Platform installation is complete, you can choose to secure the integrated Docker registry, which involves adjusting the --insecure-registry option accordingly.

2.3.5. Configuring Docker Storage

Containers and the images they are created from are stored in Docker's storage back end. This storage is ephemeral and separate from any persistent storage allocated to meet the needs of your applications.

For RHEL Atomic Host

The default storage back end for Docker on RHEL Atomic Host is a thin pool logical volume, which is supported for production environments. You must ensure that enough space is allocated for this volume per the Docker storage requirements mentioned in System Requirements.

If you do not have enough allocated, see Managing Storage with Docker Formatted Containers for details on using **docker-storage-setup** and basic instructions on storage management in RHEL Atomic Host.

For RHEL

The default storage back end for Docker on RHEL 7 is a thin pool on loopback devices, which is not supported for production use and only appropriate for proof of concept environments. For production environments, you must create a thin pool logical volume and re-configure Docker to use that volume.

You can use the **docker-storage-setup** script included with Docker to create a thin pool device and configure Docker's storage driver. This can be done after installing Docker and should be done before creating images or containers. The script reads configuration options from the **/etc/sysconfig/docker-storage-setup** file and supports three options for creating the logical volume:

- Option A) Use an additional block device.
- Option B) Use an existing, specified volume group.
- Option C) Use the remaining free space from the volume group where your root file system is located.

Option A is the most robust option, however it requires adding an additional block device to your host before configuring Docker storage. Options B and C both require leaving free space available when provisioning your host. Option C is known to cause issues with some applications, for example Red Hat Mobile Application Platform (RHMAP).

- 1. Create the docker-pool volume using one of the following three options:
 - Option A) Use an additional block device.
 In /etc/sysconfig/docker-storage-setup, set DEVS to the path of the block device you wish to use. Set VG to the volume group name you wish to create; docker-vg is a reasonable choice. For example:

```
# cat <<EOF > /etc/sysconfig/docker-storage-setup
DEVS=/dev/vdc
VG=docker-vg
EOF
```

Then run **docker-storage-setup** and review the output to ensure the **docker-pool** volume was created:

```
# docker-storage-setup
[5/1868]
Checking that no-one is using this disk right now ...
0K
Disk /dev/vdc: 31207 cylinders, 16 heads, 63 sectors/track
sfdisk: /dev/vdc: unrecognized partition table type
Old situation:
sfdisk: No partitions found
New situation:
Units: sectors of 512 bytes, counting from 0
  Device Boot
                 Start
                             End
                                   #sectors Id
                                                 System
/dev/vdc1
                  2048 31457279
                                    31455232 8e
                                                 Linux LVM
/dev/vdc2
                     0
                                                 Empty
                                          0 0
/dev/vdc3
                     0
                                          0
                                              0
                                                 Empty
/dev/vdc4
                     0
                                                 Empty
Warning: partition 1 does not start at a cylinder boundary
Warning: partition 1 does not end at a cylinder boundary
Warning: no primary partition is marked bootable (active)
This does not matter for LILO, but the DOS MBR will not boot this
```

```
Successfully wrote the new partition table
Re-reading the partition table ...
If you created or changed a DOS partition, /dev/foo7, say, then
use dd(1)
to zero the first 512 bytes: dd if=/dev/zero of=/dev/foo7 bs=512
count=1
(See fdisk(8).)
  Physical volume "/dev/vdc1" successfully created
 Volume group "docker-vg" successfully created
  Rounding up size to full physical extent 16.00 MiB
  Logical volume "docker-poolmeta" created.
  Logical volume "docker-pool" created.
 WARNING: Converting logical volume docker-vg/docker-pool and
docker-vg/docker-poolmeta to pool's data and metadata volumes.
  THIS WILL DESTROY CONTENT OF LOGICAL VOLUME (filesystem etc.)
  Converted docker-vg/docker-pool to thin pool.
  Logical volume "docker-pool" changed.
```

Option B) Use an existing, specified volume group.
 In /etc/sysconfig/docker-storage-setup, set VG to the desired volume group. For example:

```
# cat <<EOF > /etc/sysconfig/docker-storage-setup
VG=docker-vg
EOF
```

Then run **docker-storage-setup** and review the output to ensure the **docker-pool** volume was created:

```
# docker-storage-setup
Rounding up size to full physical extent 16.00 MiB
Logical volume "docker-poolmeta" created.
Logical volume "docker-pool" created.
WARNING: Converting logical volume docker-vg/docker-pool and
docker-vg/docker-poolmeta to pool's data and metadata volumes.
THIS WILL DESTROY CONTENT OF LOGICAL VOLUME (filesystem etc.)
Converted docker-vg/docker-pool to thin pool.
Logical volume "docker-pool" changed.
```

• Option C) Use the remaining free space from the volume group where your root file system is located.

Verify that the volume group where your root file system resides has the desired free space, then run **docker-storage-setup** and review the output to ensure the **docker-pool** volume was created:

```
# docker-storage-setup
Rounding up size to full physical extent 32.00 MiB
Logical volume "docker-poolmeta" created.
Logical volume "docker-pool" created.
WARNING: Converting logical volume rhel/docker-pool and
rhel/docker-poolmeta to pool's data and metadata volumes.
THIS WILL DESTROY CONTENT OF LOGICAL VOLUME (filesystem etc.)
Converted rhel/docker-pool to thin pool.
```

Logical volume "docker-pool" changed.

2. Verify your configuration. You should have a **dm.thinpooldev** value in the /etc/sysconfig/docker-storage file and a docker-pool logical volume:

IMPORTANT

Before using Docker or OpenShift Container Platform, verify that the docker-pool logical volume is large enough to meet your needs. The docker-pool volume should be 60% of the available volume group and will grow to fill the volume group via LVM monitoring.

3. Check if Docker is running:

```
# systemctl is-active docker
```

4. If Docker has not yet been started on the host, enable and start the service:

```
# systemctl enable docker
# systemctl start docker
```

If Docker is already running, re-initialize Docker:

WARNING

This will destroy any containers or images currently on the host.

```
# systemctl stop docker
# rm -rf /var/lib/docker/*
# systemctl restart docker
```

If there is any content in /var/lib/docker/, it must be deleted. Files will be present if Docker has been used prior to the installation of OpenShift Container Platform.

2.3.5.1. Reconfiguring Docker Storage

Should you need to reconfigure Docker storage after having created the **docker-pool**, you should first remove the **docker-pool** logical volume. If you are using a dedicated volume group, you should also remove the volume group and any associated physical volumes before reconfiguring **docker-storage-**

setup according to the instructions above.

See Logical Volume Manager Administration for more detailed information on LVM management.

2.3.5.2. Managing Container Logs

Sometimes a container's log file (the /var/lib/docker/containers/<hash>/<hash>-json.log file on the node where the container is running) can increase to a problematic size. You can manage this by configuring Docker's json-file logging driver to restrict the size and number of log files.

IMPORTANT

Aggregated logging is only supported using the **journald** driver in Docker. See Updating Fluentd's Log Source After a Docker Log Driver Update for more information.

Option	Purpose
log-opt max-size	Sets the size at which a new log file is created.
log-opt max-file	Sets the file on each host to configure the options.

For example, to set the maximum file size to 1MB and always keep the last three log files, edit the /etc/sysconfig/docker file to configure max-size=1M and max-file=3:

```
OPTIONS='--insecure-registry=172.30.0.0/16 --selinux-enabled --log-opt max-size=1M --log-opt max-file=3'
```

Next, restart the Docker service:

```
# systemctl restart docker
```

2.3.5.3. Viewing Available Container Logs

Container logs are stored in the /var/lib/docker/containers/<hash>/ directory on the node where the container is running. For example:

```
# ls -lh
/var/lib/docker/containers/f088349cceac173305d3e2c2e4790051799efe363842fda
b5732f51f5b001fd8/
total 2.6M
-rw-r----. 1 root root 5.6K Nov 24 00:12 config.json
-rw-r----. 1 root root 649K Nov 24 00:15
f088349cceac173305d3e2c2e4790051799efe363842fdab5732f51f5b001fd8-json.log
-rw-r----. 1 root root 977K Nov 24 00:15
f088349cceac173305d3e2c2e4790051799efe363842fdab5732f51f5b001fd8-
json.log.1
-rw-r----. 1 root root 977K Nov 24 00:15
f088349cceac173305d3e2c2e4790051799efe363842fdab5732f51f5b001fd8-
json.log.2
-rw-r----. 1 root root 1.3K Nov 24 00:12 hostconfig.json
drwx-----. 2 root root 6 Nov 24 00:12 secrets
```

See Docker's documentation for additional information on how to Configure Logging Drivers.

2.3.6. Ensuring Host Access

The quick and advanced installation methods require a user that has access to all hosts. If you want to run the installer as a non-root user, passwordless **sudo** rights must be configured on each destination host.

For example, you can generate an SSH key on the host where you will invoke the installation process:

```
# ssh-keygen
```

Do not use a password.

An easy way to distribute your SSH keys is by using a bash loop:

```
# for host in master.example.com \
   node1.example.com \
   node2.example.com; \
   do ssh-copy-id -i ~/.ssh/id_rsa.pub $host; \
   done
```

Modify the host names in the above command according to your configuration.

2.3.7. What's Next?

If you are interested in installing OpenShift Container Platform using the containerized method (optional for RHEL but required for RHEL Atomic Host), see Installing on Containerized Hosts to prepare your hosts.

When you are ready to proceed, you can install OpenShift Container Platform using the quick installation or advanced installation method.

If you are installing a stand-alone registry, continue with Installing a Stand-alone Registry.

2.4. INSTALLING ON CONTAINERIZED HOSTS

2.4.1. Overview

An RPM installation installs all services through package management and configures services to run within the same user space, while a containerized installation installs services using container images and runs separate services in individual containers.

The default method for installing OpenShift Container Platform on Red Hat Enterprise Linux (RHEL) uses RPMs.

IMPORTANT

When targeting a Red Hat Atomic Host system, the containerized method is the only available option, and is automatically selected for you based on the detection of the /run/ostree-booted file.

The following table outlines the differences between the RPM and Containerized methods:

	RPM	Containerized
Installation Method	Packages via yum	Container images via docker
Service Management	systemd	docker and systemd units
Operating System	Red Hat Enterprise Linux	Red Hat Enterprise Linux or Red Hat Atomic Host

2.4.2. Install Methods for Containerized Hosts

As with the RPM installation, you can choose between the quick and advanced install methods for the containerized install.

For the quick installation method, you can choose between the RPM or containerized method on a per host basis during the interactive installation, or set the values manually in an installation configuration file.

For the advanced installation method, you can set the Ansible variable **containerized=true** in an inventory file on a cluster-wide or per host basis.

For the disconnected installation method, to install the etcd container, you can set the Ansible variable osm_etcd_image to be the fully qualified name of the etcd image on your local registry, for example, registry.example.com/rhel7/etcd.

NOTE

When installing an environment with multiple masters, the load balancer cannot be deployed by the installation process as a container. See Advanced Installation for load balancer requirements using the native HA method.

2.4.3. Required Images

Containerized installations make use of the following images:

- openshift3/ose
- openshift3/node
- openshift3/openvswitch
- registry.access.redhat.com/rhel7/etcd

By default, all of the above images are pulled from the Red Hat Registry at registry.access.redhat.com.

If you need to use a private registry to pull these images during the installation, you can specify the registry information ahead of time. For the advanced installation method, you can set the following Ansible variables in your inventory file, as required:

```
cli_docker_additional_registries=<registry_hostname>
cli_docker_insecure_registries=<registry_hostname>
cli_docker_blocked_registries=<registry_hostname>
```

For the quick installation method, you can export the following environment variables on each target host:

```
# export 00_INSTALL_ADDITIONAL_REGISTRIES=<registry_hostname>
# export 00_INSTALL_INSECURE_REGISTRIES=<registry_hostname>
```

Blocked Docker registries cannot currently be specified using the quick installation method.

The configuration of additional, insecure, and blocked Docker registries occurs at the beginning of the installation process to ensure that these settings are applied before attempting to pull any of the required images.

2.4.4. CLI Wrappers

When using containerized installations, a CLI wrapper script is deployed on each master at /usr/local/bin/openshift. The following set of symbolic links are also provided to ease administrative tasks:

Symbolic Link	Usage
/usr/local/bin/oc	Developer CLI
/usr/local/bin/oadm	Administrative CLI
/usr/local/bin/kubectl	Kubernetes CLI

The wrapper spawns a new container on each invocation, so you may notice it run slightly slower than native CLI operations.

The wrapper scripts mount a limited subset of paths:

- ~/.kube
- /etc/origin/
- /tmp/

Be mindful of this when passing in files to be processed by the **oc** or **oadm** commands. You may find it easier to redirect the input, for example:

NOTE

The wrapper is intended only to be used to bootstrap an environment. You should install the CLI tools on another host after you have granted **cluster-admin** privileges to a user. See Managing Role Bindings and Get Started with the CLI for more information.

2.4.5. Starting and Stopping Containers

The installation process creates relevant **systemd** units which can be used to start, stop, and poll services using normal **systemctl** commands. For containerized installations, these unit names match those of an RPM installation, with the exception of the **etcd** service which is named **etcd_container**.

This change is necessary as currently RHEL Atomic Host ships with the **etcd** package installed as part of the operating system, so a containerized version is used for the OpenShift Container Platform installation instead. The installation process disables the default **etcd** service. The **etcd** package is slated to be removed from RHEL Atomic Host in the future.

2.4.6. File Paths

All OpenShift Container Platform configuration files are placed in the same locations during containerized installation as RPM based installations and will survive **os-tree** upgrades.

However, the default image stream and template files are installed at /etc/origin/examples/ for containerized installations rather than the standard /usr/share/openshift/examples/, because that directory is read-only on RHEL Atomic Host.

2.4.7. Storage Requirements

RHEL Atomic Host installations normally have a very small root file system. However, the etcd, master, and node containers persist data in the /var/lib/ directory. Ensure that you have enough space on the root file system before installing OpenShift Container Platform. See the System Requirements section for details.

2.4.8. Open vSwitch SDN Initialization

OpenShift SDN initialization requires that the Docker bridge be reconfigured and that Docker is restarted. This complicates the situation when the node is running within a container. When using the Open vSwitch (OVS) SDN, you will see the node start, reconfigure Docker, restart Docker (which restarts all containers), and finally start successfully.

In this case, the node service may fail to start and be restarted a few times, because the master services are also restarted along with Docker. The current implementation uses a workaround which relies on setting the Restart=always parameter in the Docker based systemd units.

2.5. QUICK INSTALLATION

2.5.1. Overview

The quick installation method allows you to use an interactive CLI utility, the atomic-openshift-installer command, to install OpenShift Container Platform across a set of hosts. This installer can deploy OpenShift Container Platform components on targeted hosts by either installing RPMs or running containerized services.

IMPORTANT

While RHEL Atomic Host is supported for running containerized OpenShift Container Platform services, the installer is provided by an RPM and not available by default in RHEL Atomic Host. Therefore, it must be run from a Red Hat Enterprise Linux 7 system. The host initiating the installation does not need to be intended for inclusion in the OpenShift Container Platform cluster, but it can be.

This installation method is provided to make the installation experience easier by interactively gathering the data needed to run on each host. The installer is a self-contained wrapper intended for usage on a Red Hat Enterprise Linux (RHEL) 7 system.

In addition to running interactive installations from scratch, the atomic-openshift-installer command can also be run or re-run using a predefined installation configuration file. This file can be used with the installer to:

- run an unattended installation,
- add nodes to an existing cluster,
- upgrade your cluster, or
- reinstall the OpenShift Container Platform cluster completely.

Alternatively, you can use the advanced installation method for more complex environments.

NOTE

To install OpenShift Container Platform as a stand-alone registry, see Installing a Stand-alone Registry.

2.5.2. Before You Begin

The installer allows you to install OpenShift Container Platform master and node components on a defined set of hosts.

NOTE

By default, any hosts you designate as masters during the installation process are automatically also configured as nodes so that the masters are configured as part of the OpenShift Container Platform SDN. The node component on the masters, however, are marked unschedulable, which blocks pods from being scheduled on it. After the installation, you can mark them schedulable if you want.

Before installing OpenShift Container Platform, you must first satisfy the prerequisites on your hosts, which includes verifying system and environment requirements and properly installing and configuring Docker. You must also be prepared to provide or validate the following information for each of your targeted hosts during the course of the installation:

- User name on the target host that should run the Ansible-based installation (can be root or non-root)
- Host name
- Whether to install components for master, node, or both
- Whether to use the RPM or containerized method
- Internal and external IP addresses

IMPORTANT

If you are installing OpenShift Container Platform using the containerized method (optional for RHEL but required for RHEL Atomic Host), see the Installing on Containerized Hosts topic to ensure that you understand the differences between these methods, then return to this topic to continue.

After following the instructions in the Prerequisites topic and deciding between the RPM and containerized methods, you can continue to running an interactive or unattended installation.

2.5.3. Running an Interactive Installation

NOTE

Ensure you have read through Before You Begin.

You can start the interactive installation by running:

\$ atomic-openshift-installer install

Then follow the on-screen instructions to install a new OpenShift Container Platform cluster.

After it has finished, ensure that you back up the ~/.config/openshift/installer.cfg.ymlinstallation configuration file that is created, as it is required if you later want to re-run the installation, add hosts to the cluster, or upgrade your cluster. Then, verify the installation.

2.5.4. Defining an Installation Configuration File

The installer can use a predefined installation configuration file, which contains information about your installation, individual hosts, and cluster. When running an interactive installation, an installation configuration file based on your answers is created for you in ~/.config/openshift/installer.cfg.yml. The file is created if you are instructed to exit the installation to manually modify the configuration or when the installation completes. You can also create the configuration file manually from scratch to perform an unattended installation.

Example 2.1. Installation Configuration File Specification

```
version: v2 1
variant: openshift-enterprise 2
variant_version: 3.5 3
ansible_log_path: /tmp/ansible.log 4
deployment:
   ansible_ssh_user: root 5
hosts: 6
   - ip: 10.0.0.1 7
   hostname: master-private.example.com 8
   public_ip: 24.222.0.1 9
   public_hostname: master.example.com 10
   roles: 11
        - master
        - node
   containerized: true 12
```

```
connect_to: 24.222.0.1 13
- ip: 10.0.0.2
 hostname: node1-private.example.com
 public_ip: 24.222.0.2
 public_hostname: node1.example.com
 node_labels: {'region': 'infra'} 14
 roles:
    - node
 connect_to: 10.0.0.2
- ip: 10.0.0.3
 hostname: node2-private.example.com
 public_ip: 24.222.0.3
 public_hostname: node2.example.com
 roles:
    - node
 connect_to: 10.0.0.3
roles: 15
 master:
    <variable_name1>: "<value1>" 16
    <variable_name2>: "<value2>"
 node:
    <variable_name1>: "<value1>" 17
```

- The version of this installation configuration file. As of OpenShift Container Platform 3.3, the only valid version here is **v2**.
- The OpenShift Container Platform variant to install. For OpenShift Container Platform, set this to openshift enterprise.
- A valid version of your selected variant: 3.5, 3.4, 3.3, 3.2, or 3.1. If not specified, this defaults to the latest version for the specified variant.
- Defines where the Ansible logs are stored. By default, this is the /tmp/ansible.log file.
- Defines which user Ansible uses to SSH in to remote systems for gathering facts and for the installation. By default, this is the root user, but you can set it to any user that has **sudo** privileges.
- Defines a list of the hosts onto which you want to install the OpenShift Container Platform master and node components.
- Required. Allows the installer to connect to the system and gather facts before proceeding with the install.
- 9 10 Required for unattended installations. If these details are not specified, then this information is pulled from the facts gathered by the installer, and you are asked to confirm the details. If undefined for an unattended installation, the installation fails.
- Determines the type of services that are installed. Specified as a list.
- If set to **true**, containerized OpenShift Container Platform services are run on target master and node hosts instead of installed using RPM packages. If set to **false** or unset, the default RPM method is used. RHEL Atomic Host requires the containerized method, and is automatically selected for you based on the detection of the **/run/ostree-booted** file. See Installing on Containerized Hosts for more details.

- The IP address that Ansible attempts to connect to when installing, upgrading, or uninstalling the systems. If the configuration file was auto-generated, then this is the value you first enter for the host during that interactive install process.
- Node labels can optionally be set per-host.
- Defines a dictionary of roles across the deployment.
- Any ansible variables that should only be applied to hosts assigned a role can be defined. For examples, see Configuring Ansible.

2.5.5. Running an Unattended Installation

NOTE

Ensure you have read through the Before You Begin.

Unattended installations allow you to define your hosts and cluster configuration in an installation configuration file before running the installer so that you do not have to go through all of the interactive installation questions and answers. It also allows you to resume an interactive installation you may have left unfinished, and guickly get back to where you left off.

To run an unattended installation, first define an installation configuration file at ~/.config/openshift/installer.cfg.yml. Then, run the installer with the -u flag:

\$ atomic-openshift-installer -u install

By default in interactive or unattended mode, the installer uses the configuration file located at ~/.config/openshift/installer.cfg.yml if the file exists. If it does not exist, attempting to start an unattended installation fails.

Alternatively, you can specify a different location for the configuration file using the -c option, but doing so will require you to specify the file location every time you run the installation:

\$ atomic-openshift-installer -u -c </path/to/file> install

After the unattended installation finishes, ensure that you back up the ~/.config/openshift/installer.cfg.yml file that was used, as it is required if you later want to re-run the installation, add hosts to the cluster, or upgrade your cluster. Then, verify the installation.

2.5.6. Verifying the Installation

After the installation completes:

1. If you are using a proxy, you must add the IP address of the etcd endpoints to the **openshift_no_proxy** cluster variable in your inventory file.

NOTE

If you are not using a proxy, you can skip this step.

In OpenShift Container Platform 3.4, the master connected to the etcd cluster using the host name of the etcd endpoints. In OpenShift Container Platform 3.5, the master now connects to etcd via IP address.

When configuring a cluster to use proxy settings (see Configuring Global Proxy Options), this change causes the master-to-etcd connection to be proxied as well, rather than being excluded by host name in each host's NO_PROXY setting (see Working with HTTP Proxies for more about NO_PROXY).

a. To workaround this issue, add the IP address of the etcd endpoints to the NO_PROXY environment variable on each master host's /etc/sysconfig/atomic-openshift-mastercontrollers file. For example:

```
NO_PROXY=https://<ip_address>:<port>
```

Use the IP that the master will use to contact the etcd cluster as the <ip_address>. The <port> should be 2379 if you are using standalone etcd (clustered) or 4001 for embedded etcd (single master, non-clustered etcd). The installer will be updated in a future release to handle this scenario automatically during installation and upgrades (BZ#1466783).

b. Restart the master service for the changes to take effect:

```
# systemctl restart atomic-openshift-master
```

2. Verify that the master is started and nodes are registered and reporting in **Ready** status. *On the master host*, run the following as root:

```
# oc get nodes

NAME STATUS AGE
master.example.com Ready, SchedulingDisabled 165d
node1.example.com Ready 165d
node2.example.com Ready 165d
```

- 3. To verify that the web console is installed correctly, use the master host name and the web console port number to access the web console with a web browser.

 For example, for a master host with a host name of master.openshift.com and using the
 - default port of 8443, the web console would be found at

```
https://master.openshift.com:8443/console.
```

4. Now that the install has been verified, run the following command on each master and node host to add the **atomic-openshift** packages back to the list of yum excludes on the host:

```
# atomic-openshift-excluder exclude
```

5. Then, see What's Next for the next steps on configuring your OpenShift Container Platform cluster.

2.5.7. Uninstalling OpenShift Container Platform

You can uninstall OpenShift Container Platform from all hosts in your cluster using the installer's uninstall command. By default, the installer uses the installation configuration file located at ~/.config/openshift/installer.cfg.yml if the file exists:

\$ atomic-openshift-installer uninstall

Alternatively, you can specify a different location for the configuration file using the -c option:

\$ atomic-openshift-installer -c </path/to/file> uninstall

See the advanced installation method for more options.

2.5.8. What's Next?

Now that you have a working OpenShift Container Platform instance, you can:

- Configure authentication; by default, authentication is set to Deny All.
- Configure the automatically-deployed integrated Docker registry.
- Configure the automatically-deployed router.

2.6. ADVANCED INSTALLATION

2.6.1. Overview

A reference configuration implemented using Ansible playbooks is available as the *advanced installation* method for installing a OpenShift Container Platform cluster. Familiarity with Ansible is assumed, however you can use this configuration as a reference to create your own implementation using the configuration management tool of your choosing.

IMPORTANT

While RHEL Atomic Host is supported for running containerized OpenShift Container Platform services, the advanced installation method utilizes Ansible, which is not available in RHEL Atomic Host, and must therefore be run from a RHEL 7 system. The host initiating the installation does not need to be intended for inclusion in the OpenShift Container Platform cluster, but it can be.

Alternatively, you can use the quick installation method if you prefer an interactive installation experience.

NOTE

To install OpenShift Container Platform as a stand-alone registry, see Installing a Standalone Registry.

2.6.2. Before You Begin

Before installing OpenShift Container Platform, you must first see the Prerequisites and Host Preparation topics to prepare your hosts. This includes verifying system and environment requirements per component type and properly installing and configuring Docker. It also includes installing Ansible version 2.2.0 or later, as the advanced installation method is based on Ansible playbooks and as such requires directly invoking Ansible.

If you are interested in installing OpenShift Container Platform using the containerized method (optional for RHEL but required for RHEL Atomic Host), see Installing on Containerized Hosts to

ensure that you understand the differences between these methods, then return to this topic to continue.

For large-scale installs, including suggestions for optimizing install time, see the Scaling and Performance Guide.

After following the instructions in the Prerequisites topic and deciding between the RPM and containerized methods, you can continue in this topic to Configuring Ansible Inventory Files.

2.6.3. Configuring Ansible Inventory Files

The /etc/ansible/hosts file is Ansible's inventory file for the playbook used to install OpenShift Container Platform. The inventory file describes the configuration for your OpenShift Container Platform cluster. You must replace the default contents of the file with your desired configuration.

The following sections describe commonly-used variables to set in your inventory file during an advanced installation, followed by example inventory files you can use as a starting point for your installation.

Many of the Ansible variables described are optional. Accepting the default values should suffice for development environments, but for production environments it is recommended you read through and become familiar with the various options available.

The example inventories describe various environment topographies, including using multiple masters for high availability. You can choose an example that matches your requirements, modify it to match your own environment, and use it as your inventory file when running the advanced installation.

Image Version Policy

Images require a version number policy in order to maintain updates. See the Image Version Tag Policy section in the Architecture Guide for more information.

2.6.3.1. Configuring Cluster Variables

To assign environment variables during the Ansible install that apply more globally to your OpenShift Container Platform cluster overall, indicate the desired variables in the /etc/ansible/hosts file on separate, single lines within the [OSEv3:vars] section. For example:

```
[OSEv3:vars]

openshift_master_identity_providers=[{'name': 'htpasswd_auth',
  'login': 'true', 'challenge': 'true',
  'kind': 'HTPasswdPasswordIdentityProvider',
  'filename': '/etc/origin/master/htpasswd'}]

openshift_master_default_subdomain=apps.test.example.com
```

The following table describes variables for use with the Ansible installer that can be assigned clusterwide:

Table 2.9. Cluster Variables

Variable	Purpose

Variable	Purpose
ansible_ssh_user	This variable sets the SSH user for the installer to use and defaults to root . This user should allow SSH-based authentication without requiring a password. If using SSH key-based authentication, then the key should be managed by an SSH agent.
ansible_become	If ansible_ssh_user is notroot, this variable must be set to true and the user must be configured for passwordless sudo.
debug_level	This variable sets which INFO messages are logged to the systemd-journald.service. Set one of the following: • 0 to log errors and warnings only • 2 to log normal information (This is the default level.) • 4 to log debugging-level information • 6 to log API-level debugging information (request / response) • 8 to log body-level API debugging information For more information on debug log levels, see Configuring Logging Levels.
containerized	If set to true , containerized OpenShift Container Platform services are run on all target master and node hosts in the cluster instead of installed using RPM packages. If set to false or unset, the default RPM method is used. RHEL Atomic Host requires the containerized method, and is automatically selected for you based on the detection of the /run/ostree-booted file. See Installing on Containerized Hosts for more details. Containerized installations are supported starting in OpenShift Container Platform 3.1.1.
openshift_master_audit_config	This variable enables API service auditing. See Audit Configuration for more information.
openshift_master_cluster_hostname	This variable overrides the host name for the cluster, which defaults to the host name of the master.

Variable	Purpose
openshift_master_cluster_public_host name	This variable overrides the public host name for the cluster, which defaults to the host name of the master.
openshift_master_cluster_method	Optional. This variable defines the HA method when deploying multiple masters. Supports the native method. See Multiple Masters for more information.
openshift_rolling_restart_mode	This variable enables rolling restarts of HA masters (i.e., masters are taken down one at a time) when running the upgrade playbook directly. It defaults to services, which allows rolling restarts of services on the masters. It can instead be set to system, which enables rolling, full system restarts and also works for single master clusters.
os_sdn_network_plugin_name	This variable configures which OpenShift SDN plugin to use for the pod network, which defaults to redhat/openshift-ovs-subnet for the standard SDN plug-in. Set the variable to redhat/openshift-ovs-multitenant to use the multitenant plug-in.
openshift_master_identity_providers	This variable overrides the identity provider, which defaults to Deny All.
openshift_master_named_certificates	These variables are used to configure custom
openshift_master_overwrite_named_cer tificates	certificates which are deployed as part of the installation. See Configuring Custom Certificates for more information.
openshift_hosted_registry_cert_expir e_days	Validity of the auto-generated registry certificate in days. Defaults to 730 (2 years).
openshift_ca_cert_expire_days	Validity of the auto-generated CA certificate in days. Defaults to 1825 (5 years).
openshift_node_cert_expire_days	Validity of the auto-generated node certificate in days. Defaults to 730 (2 years).
openshift_master_cert_expire_days	Validity of the auto-generated master certificate in days. Defaults to 730 (2 years).
etcd_ca_default_days	Validity of the auto-generated external etcd certificates in days. Controls validity for etcd CA, peer, server and client certificates. Defaults to 1825 (5 years).

Variable	Purpose
os_firewall_use_firewalld	Set to true to use firewalld instead of the default iptables. Not available on RHEL Atomic Host. See the Configuring the Firewall section for more information.
openshift_master_session_name	
openshift_master_session_max_seconds	
openshift_master_session_auth_secret s	These variables override defaults for session options in the OAuth configuration. See Configuring Session Options for more information.
openshift_master_session_encryption_ secrets	
openshift_portal_net	This variable configures the subnet in which services will be created within the OpenShift Container Platform SDN. This network block should be private and must not conflict with any existing network blocks in your infrastructure to which pods, nodes, or the master may require access to, or the installation will fail. Defaults to 172.30.0.0/16, and cannot be re-configured after deployment. If changing from the default, avoid 172.17.0.0/16, which the docker0 network bridge uses by default, or modify the docker0 network.
openshift_master_default_subdomain	This variable overrides the default subdomain to use for exposed routes.
openshift_node_proxy_mode	This variable specifies the service proxy mode to use: either iptables for the default, pure-iptables implementation, or userspace for the user space proxy.
osm_default_node_selector	This variable overrides the node selector that projects will use by default when placing pods.
osm_cluster_network_cidr	This variable overrides the SDN cluster network CIDR block. This is the network from which pod IPs are assigned. This network block should be a private block and must not conflict with existing network blocks in your infrastructure to which pods, nodes, or the master may require access. Defaults to 10.128.0.0/14 and cannot be arbitrarily reconfigured after deployment, although certain changes to it can be made in the SDN master configuration.

Variable	Purpose
osm_host_subnet_length	This variable specifies the size of the per host subnet allocated for pod IPs by OpenShift Container Platform SDN. Defaults to 9 which means that a subnet of size /23 is allocated to each host; for example, given the default 10.128.0.0/14 cluster network, this will allocate 10.128.0.0/23, 10.128.2.0/23, 10.128.4.0/23, and so on. This cannot be re-configured after deployment.
openshift_use_flannel	This variable enables flannel as an alternative networking layer instead of the default SDN. If enabling flannel , disable the default SDN with the openshift_use_openshift_sdn variable. For more information, see Using Flannel.
openshift_docker_additional_registri es	OpenShift Container Platform adds the specified additional registry or registries to the docker configuration.
openshift_docker_insecure_registries	OpenShift Container Platform adds the specified additional insecure registry or registries to the docker configuration.
openshift_docker_blocked_registries	OpenShift Container Platform adds the specified blocked registry or registries to the docker configuration.
openshift_hosted_metrics_public_url	This variable sets the host name for integration with the metrics console by overriding metricsPublicURL in the master configuration for cluster metrics. If you alter this variable, ensure the host name is accessible via your router. See Configuring Cluster Metrics for details.

2.6.3.2. Configuring Deployment Type

Various defaults used throughout the playbooks and roles used by the installer are based on the deployment type configuration (usually defined in an Ansible inventory file).

Ensure the deployment_type parameter in your inventory file's [OSEv3:vars] section is set to openshift-enterprise to install the OpenShift Container Platform variant:

[OSEv3:vars]
deployment_type=openshift-enterprise

2.6.3.3. Configuring Host Variables

To assign environment variables to hosts during the Ansible installation, indicate the desired variables in the /etc/ansible/hosts file after the host entry in the [masters] or [nodes] sections. For example:

[masters]
ec2-52-6-179-239.compute-1.amazonaws.com openshift_public_hostname=ose3master.public.example.com

The following table describes variables for use with the Ansible installer that can be assigned to individual host entries:

Table 2.10. Host Variables

Variable	Purpose
openshift_hostname	This variable overrides the internal cluster host name for the system. Use this when the system's default IP address does not resolve to the system host name.
openshift_public_hostname	This variable overrides the system's public host name. Use this for cloud installations, or for hosts on networks using a network address translation (NAT).
openshift_ip	This variable overrides the cluster internal IP address for the system. Use this when using an interface that is not configured with the default route.
openshift_public_ip	This variable overrides the system's public IP address. Use this for cloud installations, or for hosts on networks using a network address translation (NAT).
containerized	If set to true, containerized OpenShift Container Platform services are run on the target master and node hosts instead of installed using RPM packages. If set to false or unset, the default RPM method is used. RHEL Atomic Host requires the containerized method, and is automatically selected for you based on the detection of the /run/ostree-booted file. See Installing on Containerized Hosts for more details. Containerized installations are supported starting in OpenShift Container Platform 3.1.1.
openshift_node_labels	This variable adds labels to nodes during installation. See Configuring Node Host Labels for more details.

Variable	Purpose
openshift_node_kubelet_args	This variable is used to configure kubeletArguments on nodes, such as arguments used in container and image garbage collection, and to specify resources per node kubeletArguments are key value pairs that are passed directly to the Kubelet that match the Kubelet's command line arguments kubeletArguments are not migrated or validated and may become invalid if used. These values override other settings in node configuration which may cause invalid configurations. Example usage: {'image-gc-high-threshold': ['90'],'image-gc-low-threshold': ['80']}.
openshift_hosted_router_selector	Default node selector for automatically deploying router pods. See Configuring Node Host Labels for details.
openshift_registry_selector	Default node selector for automatically deploying registry pods. See Configuring Node Host Labels for details.
openshift_docker_options	This variable configures additional Docker options within /etc/sysconfig/docker, such as options used in Managing Container Logs. Example usage: "log-driver json-filelog-opt max-size=1Mlog-opt max-file=3".
openshift_schedulable	This variable configures whether the host is marked as a schedulable node, meaning that it is available for placement of new pods. See Configuring Schedulability on Masters.

2.6.3.4. Configuring Master API and Console Ports

To configure the default ports used by the master API and web console, configure the following variables in the /etc/ansible/hosts file:

Table 2.11. Master API and Console Ports

Variable	Purpose
openshift_master_api_port	This variable sets the port number to access the OpenShift Container Platform API.
openshift_master_console_port	This variable sets the console port number to access the OpenShift Container Platform console with a web browser.

For example:

openshift_master_api_port=3443
openshift_master_console_port=8756

2.6.3.5. Configuring Cluster Pre-install Checks

Pre-install checks are a set of diagnostic tasks that run as part of the <code>openshift_health_checker</code> Ansible role. They run prior to an Ansible installation of OpenShift Container Platform, ensure that required inventory values are set, and identify potential issues on a host that can prevent or interfere with a successful installation.

The following table describes available pre-install checks that will run before every Ansible installation of OpenShift Container Platform:

Table 2.12. Pre-install Checks

Check Name	Purpose
memory_availability	This check ensures that a host has the recommended amount of memory for the specific deployment of OpenShift Container Platform. Default values have been derived from the latest installation documentation. A user-defined value for minimum memory requirements may be set by setting the openshift_check_min_host_memory_gb cluster variable in your inventory file.
disk_availability	This check only runs on etcd, master, and node hosts. It ensures that the mount path for an OpenShift Container Platform installation has sufficient disk space remaining. Recommended disk values are taken from the latest installation documentation. A user-defined value for minimum disk space requirements may be set by setting openshift_check_min_host_disk_gb cluster variable in your inventory file.
docker_storage	Only runs on hosts that depend on the docker daemon (nodes and containerized installations). Checks that docker's total usage does not exceed a user-defined limit. If no user-defined limit is set, docker's maximum usage threshold defaults to 90% of the total size available. The threshold limit for total percent usage can be set with a variable in your inventory file: max_thinpool_data_usage_percent=90. A user-defined limit for maximum thinpool usage may be set by setting the max_thinpool_data_usage_percent cluster variable in your inventory file.

Check Name	Purpose
docker_storage_driver	Ensures that the docker daemon is using a storage driver supported by OpenShift Container Platform. If the devicemapper storage driver is being used, the check additionally ensures that a loopback device is not being used.
docker_image_availability	Attempts to ensure that images required by an OpenShift Container Platform installation are available either locally or in at least one of the configured container image registries on the host machine.
package_version	Runs on yum-based systems determining if multiple releases of a required OpenShift Container Platform package are available. Having multiple releases of a package available during an enterprise installation of OpenShift suggests that there are multiple yum repositories enabled for different releases, which may lead to installation problems. This check is skipped if the openshift_release variable is not defined in the inventory file.
package_availability	Runs prior to non-containerized installations of OpenShift Container Platform. Ensures that RPM packages required for the current installation are available.
package_update	Checks whether a yum update or package installation will succeed, without actually performing it or running yum on the host.

To disable specific pre-install checks, include the variable **openshift_disable_check** with a comma-delimited list of check names in your inventory file. For example:

openshift_disable_check=memory_availability, disk_availability

A similar set of checks meant to run for diagnostic on existing clusters can be found in Additional Diagnostic Checks via Ansible. Another set of checks for checking certificate expiration can be found in Redeploying Certificates.

2.6.3.6. Configuring System Containers

IMPORTANT

All system container components are Technology Preview features in OpenShift Container Platform 3.6. They must not be used in production and they are not supported for upgrades to OpenShift Container Platform 3.6. During this phase, they are only meant for use with new cluster installations in non-production environments.

System containers provide a way to containerize services that need to run before the **docker** daemon is running. They are Docker-formatted containers that use:

- OSTree for storage,
- runC for the runtime,
- systemd for service management, and
- skopeo for searching.

System containers are therefore stored and run outside of the traditional **docker** service. For more details on system container technology, see Running System Containers in the *Red Hat Enterprise Linux Atomic Host: Managing Containers* documentation.

You can configure your OpenShift Container Platform installation to run certain components as system containers instead of their RPM or standard containerized methods. Currently, the **docker** and etcd components can be run as system containers in OpenShift Container Platform.

WARNING

System containers are currently OS-specific because they require specific versions of atomic and systemd. For example, different system containers are created for RHEL, Fedora, or CentOS. Ensure that the system containers you are using match the OS of the host they will run on. OpenShift Container Platform only supports RHEL and RHEL Atomic as the host OS, so by default system containers built for RHEL are used.

2.6.3.6.1. Running Docker as a System Container

IMPORTANT

All system container components are Technology Preview features in OpenShift Container Platform 3.6. They must not be used in production and they are not supported for upgrades to OpenShift Container Platform 3.6. During this phase, they are only meant for use with new cluster installations in non-production environments.

The traditional method for using **docker** in an OpenShift Container Platform cluster is an RPM package installation. For Red Hat Enterprise Linux (RHEL) systems, it must be specifically installed; for RHEL Atomic Host systems, it is provided by default.

However, you can configure your OpenShift Container Platform installation to alternatively run docker on node hosts as a system container. When using the system container method, the container-engine container image and systemd service is used on the host instead of the docker package and service.

To run docker as a system container:

1. Because the default storage back end for Docker on RHEL 7 is a thin pool on loopback devices, for any RHEL systems you must still configure a thin pool logical volume for docker to use

before running the OpenShift Container Platform installation. You can skip these steps for any RHEL Atomic Host systems.

For any RHEL systems, perform the steps described in the following sections:

- i. Installing Docker
- ii. Configuring Docker Storage

After completing the storage configuration steps, you can leave the RPM installed.

2. Set the following cluster variable to **True** in your inventory file in the **[OSEv3:vars]** section:

```
openshift_docker_use_system_container=True
```

When using the system container method, the following inventory variables for docker are ignored:

- docker_version
- docker_upgrade

Further, the following inventory variable must not be used:

• openshift_docker_options

You can also force **docker** in the system container to use a specific container registry and repository when pulling the **container-engine** image instead of from the default **registry.access.redhat.com/openshift3/**. To do so, set the following cluster variable in your inventory file in the [OSEv3:vars] section:

openshift_docker_systemcontainer_image_registry_override="registry.example
.com/myrepo/"

2.6.3.6.2. Running etcd as a System Container

IMPORTANT

All system container components are Technology Preview features in OpenShift Container Platform 3.6. They must not be used in production and they are not supported for upgrades to OpenShift Container Platform 3.6. During this phase, they are only meant for use with new cluster installations in non-production environments.

When using the RPM-based installation method for OpenShift Container Platform, etcd is installed using RPM packages on any RHEL systems. When using the containerized installation method, the rhe17/etcd image is used instead for RHEL or RHEL Atomic Hosts.

However, you can configure your OpenShift Container Platform installation to alternatively run etcd as a system container. Whereas the standard containerized method uses a systemd service named etcd_container, the system container method uses the service name etcd, same as the RPM-based method. The data directory for etcd using this method is /var/lib/etcd/etcd.etcd/etcd.etcd/member.

To run etcd as a system container, set the following cluster variable in your inventory file in the [OSEv3:vars] section:

openshift_use_etcd_system_container=True

2.6.3.7. Configuring a Registry Location

If you are using an image registry other than the default at registry.access.redhat.com, specify the desired registry within the /etc/ansible/hosts file.

oreg_url=example.com/openshift3/ose-\${component}:\${version}
openshift_examples_modify_imagestreams=true

Table 2.13. Registry Variables

Variable	Purpose
oreg_url	Set to the alternate image location. Necessary if you are not using the default registry at registry.access.redhat.com.
openshift_examples_modify_imagestrea ms	Set to true if pointing to a registry other than the default. Modifies the image stream location to the value of oreg_url .

2.6.3.8. Configuring Global Proxy Options

If your hosts require use of a HTTP or HTTPS proxy in order to connect to external hosts, there are many components that must be configured to use the proxy, including masters, Docker, and builds. Node services only connect to the master API requiring no external access and therefore do not need to be configured to use a proxy.

In order to simplify this configuration, the following Ansible variables can be specified at a cluster or host level to apply these settings uniformly across your environment.

NOTE

See Configuring Global Build Defaults and Overrides for more information on how the proxy environment is defined for builds.

Table 2.14. Cluster Proxy Variables

Variable	Purpose
openshift_http_proxy	This variable specifies the HTTP_PROXY environment variable for masters and the Docker daemon.
openshift_https_proxy	This variable specifices the HTTPS_PROXY environment variable for masters and the Docker daemon.

Variable	Purpose
openshift_no_proxy	This variable is used to set the NO_PROXY environment variable for masters and the Docker daemon. This value should be set to a comma separated list of host names or wildcard host names that should not use the defined proxy. This list will be augmented with the list of all defined OpenShift Container Platform host names by default.
openshift_generate_no_proxy_hosts	This boolean variable specifies whether or not the names of all defined OpenShift hosts and *.cluster.local should be automatically appended to the NO_PROXY list. Defaults to true; set it to false to override this option.
openshift_builddefaults_http_proxy	This variable defines the HTTP_PROXY environment variable inserted into builds using the BuildDefaults admission controller. If openshift_http_proxy is set, this variable will inherit that value; you only need to set this if you want your builds to use a different value.
openshift_builddefaults_https_proxy	This variable defines the HTTPS_PROXY environment variable inserted into builds using the BuildDefaults admission controller. If openshift_https_proxy is set, this variable will inherit that value; you only need to set this if you want your builds to use a different value.
openshift_builddefaults_no_proxy	This variable defines the NO_PROXY environment variable inserted into builds using the BuildDefaults admission controller. If openshift_no_proxy is set, this variable will inherit that value; you only need to set this if you want your builds to use a different value.
openshift_builddefaults_git_http_pro xy	This variable defines the HTTP proxy used by git clone operations during a build, defined using the BuildDefaults admission controller. If openshift_builddefaults_http_proxy is set, this variable will inherit that value; you only need to set this if you want your git clone operations to use a different value.
openshift_builddefaults_git_https_pr oxy	This variable defines the HTTPS proxy used by git clone operations during a build, defined using the BuildDefaults admission controller. If openshift_builddefaults_https_proxy is set, this variable will inherit that value; you only need to set this if you want your git clone operations to use a different value.

2.6.3.9. Configuring the Firewall

IMPORTANT

If you are changing the default firewall, ensure that each host in your cluster is using the same firewall type to prevent inconsistencies.

NOTE

While iptables is the default firewall, firewalld is recommended for new installations.

OpenShift Container Platform uses iptables as the default firewall, but you can configure your cluster to use firewalld during the install process.

Because iptables is the default firewall, OpenShift Container Platform is designed to have it configured automatically. However, iptables rules can break OpenShift Container Platform if not configured correctly. The advantages of firewalld include allowing multiple objects to safely share the firewall rules.

To use firewalld as the firewall for an OpenShift Container Platform installation, add the os_firewall_use_firewalld variable to the list of configuration variables in the Ansible host file at install:

```
[0SEv3:vars]
os_firewall_use_firewalld=True
```

2.6.3.10. Configuring Schedulability on Masters

Any hosts you designate as masters during the installation process should also be configured as nodes so that the masters are configured as part of the OpenShift SDN. You must do so by adding entries for these hosts to the [nodes] section:

```
[nodes]
master.example.com
```

In order to ensure that your masters are not burdened with running pods, they are automatically marked unschedulable by default by the installer, meaning that new pods cannot be placed on the hosts. This is the same as setting the openshift_schedulable=false host variable.

You can manually set a master host to schedulable during installation using the openshift_schedulable=true host variable, though this is not recommended in production environments:

```
[nodes]
master.example.com openshift_schedulable=true
```

If you want to change the schedulability of a host post-installation, see Marking Nodes as Unschedulable or Schedulable.

2.6.3.11. Configuring Node Host Labels

You can assign labels to node hosts during the Ansible install by configuring the /etc/ansible/hosts file. Labels are useful for determining the placement of pods onto nodes using the scheduler. Other

than region=infra (discussed in Configuring Dedicated Infrastructure Nodes), the actual label names and values are arbitrary and can be assigned however you see fit per your cluster's requirements.

To assign labels to a node host during an Ansible install, use the openshift_node_labels variable with the desired labels added to the desired node host entry in the [nodes] section. In the following example, labels are set for a region called primary and a zone called east:

```
[nodes]
node1.example.com openshift_node_labels="{'region': 'primary', 'zone':
'east'}"
```

2.6.3.11.1. Configuring Dedicated Infrastructure Nodes

The openshift_router_selector and openshift_registry_selector Ansible settings determine the label selectors used when placing registry and router pods. They are set to region=infra by default:

```
# default selectors for router and registry services
# openshift_router_selector='region=infra'
# openshift_registry_selector='region=infra'
```

The default router and registry will be automatically deployed during installation if nodes exist in the [nodes] section that match the selector settings. For example:

```
[nodes]
infra-node1.example.com openshift_node_labels="{'region': 'infra','zone':
'default'}"
```

IMPORTANT

The registry and router are only able to run on node hosts with the region=infra label. Ensure that at least one node host in your OpenShift Container Platform environment has the region=infra label.

It is recommended for production environments that you maintain dedicated infrastructure nodes where the registry and router pods can run separately from pods used for user applications.

As described in Configuring Schedulability on Masters, master hosts are marked unschedulable by default. If you label a master host with region=infra and have no other dedicated infrastructure nodes, you must also explicitly mark these master hosts as schedulable. Otherwise, the registry and router pods cannot be placed anywhere:

```
[nodes]
master.example.com openshift_node_labels="{'region': 'infra','zone':
  'default'}" openshift_schedulable=true
```

2.6.3.12. Configuring Session Options

Session options in the OAuth configuration are configurable in the inventory file. By default, Ansible populates a sessionSecretsFile with generated authentication and encryption secrets so that sessions generated by one master can be decoded by the others. The default location is

/etc/origin/master/session-secrets.yaml, and this file will only be re-created if deleted on all masters.

You can set the session name and maximum number of seconds with openshift_master_session_name and openshift_master_session_max_seconds:

```
openshift_master_session_name=ssn
openshift_master_session_max_seconds=3600
```

If provided, openshift_master_session_auth_secrets and openshift_master_encryption_secrets must be equal length.

For **openshift_master_session_auth_secrets**, used to authenticate sessions using HMAC, it is recommended to use secrets with 32 or 64 bytes:

```
openshift_master_session_auth_secrets=['DONT+USE+THIS+SECRET+b4NV+pmZNSO']
```

For **openshift_master_encryption_secrets**, used to encrypt sessions, secrets must be 16, 24, or 32 characters long, to select AES-128, AES-192, or AES-256:

```
openshift_master_session_encryption_secrets=
['DONT+USE+THIS+SECRET+b4NV+pmZNS0']
```

2.6.3.13. Configuring Custom Certificates

Custom serving certificates for the public host names of the OpenShift Container Platform API and web console can be deployed during an advanced installation and are configurable in the inventory file.

NOTE

Custom certificates should only be configured for the host name associated with the publicMasterURL which can be set using

openshift_master_cluster_public_hostname. Using a custom serving certificate
for the host name associated with the masterURL

(openshift_master_cluster_hostname) will result in TLS errors as infrastructure components will attempt to contact the master API using the internal masterURL host.

Certificate and key file paths can be configured using the openshift_master_named_certificates cluster variable:

```
openshift_master_named_certificates=[{"certfile": "/path/to/custom1.crt",
    "keyfile": "/path/to/custom1.key"}]
```

File paths must be local to the system where Ansible will be run. Certificates are copied to master hosts and are deployed within the /etc/origin/master/named_certificates/ directory.

Ansible detects a certificate's **Common Name** and **Subject Alternative Names**. Detected names can be overridden by providing the "names" key when setting openshift_master_named_certificates:

```
openshift_master_named_certificates=[{"certfile": "/path/to/custom1.crt",
    "keyfile": "/path/to/custom1.key", "names": ["public-master-host.com"]}]
```

Certificates configured using openshift_master_named_certificates are cached on masters, meaning that each additional Ansible run with a different set of certificates results in all previously deployed certificates remaining in place on master hosts and within the master configuration file.

If you would like openshift_master_named_certificates to be overwritten with the provided value (or no value), specify the openshift_master_overwrite_named_certificates cluster variable:

```
openshift_master_overwrite_named_certificates=true
```

For a more complete example, consider the following cluster variables in an inventory file:

```
openshift_master_cluster_method=native
openshift_master_cluster_hostname=lb.openshift.com
openshift_master_cluster_public_hostname=custom.openshift.com
```

To overwrite the certificates on a subsequent Ansible run, you could set the following:

```
openshift_master_named_certificates=[{"certfile":
   "/root/STAR.openshift.com.crt", "keyfile": "/root/STAR.openshift.com.key",
   "names": ["custom.openshift.com"]}]
openshift_master_overwrite_named_certificates=true
```

2.6.3.14. Configuring Certificate Validity

By default, the certificates used to govern the etcd, master, and kubelet expire after two to five years. The validity (length in days until they expire) for the auto-generated registry, CA, node, and master certificates can be configured during installation using the following variables (default values shown):

```
[OSEv3:vars]

openshift_hosted_registry_cert_expire_days=730
openshift_ca_cert_expire_days=1825
openshift_node_cert_expire_days=730
openshift_master_cert_expire_days=730
etcd_ca_default_days=1825
```

These values are also used when redeploying certificates via Ansible post-installation.

2.6.3.15. Configuring Cluster Metrics

Cluster metrics are not set to automatically deploy by default. Set the following to enable cluster metrics when using the advanced install:

```
[OSEv3:vars]
openshift_hosted_metrics_deploy=true
openshift_hosted_metrics_deployer_version=v3.5
```

The OpenShift Container Platform web console uses the data coming from the Hawkular Metrics service to display its graphs. The metrics public URL can be set during cluster installation using the openshift_hosted_metrics_public_url Ansible variable, which defaults to:

```
https://hawkular-metrics.
{{openshift_master_default_subdomain}}/hawkular/metrics
```

If you alter this variable, ensure the host name is accessible via your router.

2.6.3.15.1. Configuring Metrics Storage

The openshift_metrics_cassandra_storage_type variable must be set in order to use persistent storage for metrics. If openshift_metrics_cassandra_storage_type is not set, then cluster metrics data is stored in an EmptyDir volume, which will be deleted when the Cassandra pod terminates.

There are three options for enabling cluster metrics storage when using the advanced install:

Option A: NFS Host Group

When the following variables are set, an NFS volume is created during an advanced install with path <nfs_directory>/<volume_name> on the host within the [nfs] host group. For example, the volume path using these options would be /exports/metrics:

```
[OSEv3:vars]

openshift_hosted_metrics_storage_kind=nfs
openshift_hosted_metrics_storage_access_modes=['ReadWriteOnce']
openshift_hosted_metrics_storage_nfs_directory=/exports
openshift_hosted_metrics_storage_nfs_options='*(rw,root_squash)'
openshift_hosted_metrics_storage_volume_name=metrics
openshift_hosted_metrics_storage_volume_size=10Gi
```

Option B: External NFS Host

To use an external NFS volume, one must already exist with a path of <nfs_directory>/<volume_name> on the storage host.

```
[OSEv3:vars]

openshift_hosted_metrics_storage_kind=nfs
openshift_hosted_metrics_storage_access_modes=['ReadWriteOnce']
openshift_hosted_metrics_storage_host=nfs.example.com
openshift_hosted_metrics_storage_nfs_directory=/exports
openshift_hosted_metrics_storage_volume_name=metrics
openshift_hosted_metrics_storage_volume_size=10Gi
```

The remote volume path using the following options would be nfs.example.com:/exports/metrics.

Option C: Dynamic

Use the following variable if your OpenShift Container Platform environment supports dynamic volume provisioning for your cloud provider:

```
[OSEv3:vars]
openshift_metrics_cassandra_storage_type=dynamic
```

2.6.3.16. Configuring Cluster Logging

Cluster logging is not set to automatically deploy by default. Set the following to enable cluster logging when using the advanced installation method:

```
[OSEv3:vars]
openshift_hosted_logging_deploy=true
openshift_hosted_logging_deployer_version=v3.5
```

2.6.3.16.1. Configuring Logging Storage

The openshift_hosted_logging_storage_kind variable must be set in order to use persistent storage for logging. If openshift_hosted_logging_storage_kind is not set, then cluster logging data is stored in an EmptyDir volume, which will be deleted when the Elasticsearch pod terminates.

There are three options for enabling cluster logging storage when using the advanced install:

Option A: NFS Host Group

When the following variables are set, an NFS volume is created during an advanced install with path <nfs_directory>/<volume_name> on the host within the [nfs] host group. For example, the volume path using these options would be /exports/logging:

```
[OSEv3:vars]

openshift_hosted_logging_storage_kind=nfs
openshift_hosted_logging_storage_access_modes=['ReadWriteOnce']
openshift_hosted_logging_storage_nfs_directory=/exports
openshift_hosted_logging_storage_nfs_options='*(rw,root_squash)'
openshift_hosted_logging_storage_volume_name=logging
openshift_hosted_logging_storage_volume_size=10Gi
```

Option B: External NFS Host

To use an external NFS volume, one must already exist with a path of <nfs_directory>/<volume_name> on the storage host.

```
[OSEv3:vars]

openshift_hosted_logging_storage_kind=nfs
openshift_hosted_logging_storage_access_modes=['ReadWriteOnce']
openshift_hosted_logging_storage_host=nfs.example.com
openshift_hosted_logging_storage_nfs_directory=/exports
openshift_hosted_logging_storage_volume_name=logging
openshift_hosted_logging_storage_volume_size=10Gi
```

The remote volume path using the following options would be *nfs.example.com:/exports/logging*.

Option C: Dynamic

Use the following variable if your OpenShift Container Platform environment supports dynamic volume provisioning for your cloud provider:

```
[OSEv3:vars]
openshift_hosted_logging_storage_kind=dynamic
```

2.6.4. Example Inventory Files

2.6.4.1. Single Master Examples

You can configure an environment with a single master and multiple nodes, and either a single embedded **etcd** or multiple external **etcd** hosts.

NOTE

Moving from a single master cluster to multiple masters after installation is not supported.

Single Master and Multiple Nodes

The following table describes an example environment for a single master (with embedded etcd) and two nodes:

Host Name	Infrastructure Component to Install
master.example.com	Master and node
node1.example.com	Node
node2.example.com	

You can see these example hosts present in the [masters] and [nodes] sections of the following example inventory file:

Single Master and Multiple Nodes Inventory File

```
# Create an OSEv3 group that contains the masters and nodes groups
[OSEv3:children]
masters
nodes
# Set variables common for all OSEv3 hosts
[OSEv3:vars]
# SSH user, this user should allow ssh based auth without requiring a
password
ansible_ssh_user=root
# If ansible_ssh_user is not root, ansible_become must be set to true
#ansible_become=true
deployment_type=openshift-enterprise
# uncomment the following to enable htpasswd authentication; defaults to
DenyAllPasswordIdentityProvider
#openshift_master_identity_providers=[{'name': 'htpasswd_auth', 'login':
'true', 'challenge': 'true', 'kind': 'HTPasswdPasswordIdentityProvider',
'filename': '/etc/origin/master/htpasswd'}]
# host group for masters
```

```
[masters]
master.example.com

# host group for nodes, includes region info
[nodes]
master.example.com
node1.example.com openshift_node_labels="{'region': 'primary', 'zone':
    'east'}"
node2.example.com openshift_node_labels="{'region': 'primary', 'zone':
    'west'}"
infra-node1.example.com openshift_node_labels="{'region': 'infra', 'zone':
    'default'}"
infra-node2.example.com openshift_node_labels="{'region': 'infra', 'zone':
    'default'}"
```

To use this example, modify the file to match your environment and specifications, and save it as /etc/ansible/hosts.

Single Master, Multiple etcd, and Multiple Nodes

The following table describes an example environment for a single master, three etcd hosts, and two nodes:

Host Name	Infrastructure Component to Install
master.example.com	Master and node
etcd1.example.com	etcd
etcd2.example.com	
etcd3.example.com	
node1.example.com	Node
node2.example.com	

NOTE

When specifying multiple **etcd** hosts, external **etcd** is installed and configured. Clustering of OpenShift Container Platform's embedded **etcd** is not supported.

You can see these example hosts present in the [masters], [nodes], and [etcd] sections of the following example inventory file:

Single Master, Multiple etcd, and Multiple Nodes Inventory File

```
# Create an OSEv3 group that contains the masters, nodes, and etcd groups
[OSEv3:children]
masters
nodes
etcd
```

```
# Set variables common for all OSEv3 hosts
[OSEv3:vars]
ansible ssh user=root
deployment_type=openshift-enterprise
# uncomment the following to enable htpasswd authentication; defaults to
DenyAllPasswordIdentityProvider
#openshift_master_identity_providers=[{'name': 'htpasswd_auth', 'login':
'true', 'challenge': 'true', 'kind': 'HTPasswdPasswordIdentityProvider',
'filename': '/etc/origin/master/htpasswd'}]
# host group for masters
[masters]
master.example.com
# host group for etcd
[etcd]
etcd1.example.com
etcd2.example.com
etcd3.example.com
# host group for nodes, includes region info
[nodes]
master.example.com
node1.example.com openshift_node_labels="{'region': 'primary', 'zone':
'east'}"
node2.example.com openshift_node_labels="{'region': 'primary', 'zone':
'west'}"
infra-node1.example.com openshift_node_labels="{'region': 'infra', 'zone':
'default'}"
infra-node2.example.com openshift_node_labels="{'region': 'infra', 'zone':
'default'}"
```

To use this example, modify the file to match your environment and specifications, and save it as /etc/ansible/hosts.

2.6.4.2. Multiple Masters Examples

You can configure an environment with multiple masters, multiple **etcd** hosts, and multiple nodes. Configuring multiple masters for high availability (HA) ensures that the cluster has no single point of failure.

NOTE

Moving from a single master cluster to multiple masters after installation is not supported.

When configuring multiple masters, the advanced installation supports the following high availability (HA) method:

native

Leverages the native HA master capabilities built into OpenShift Container Platform and can be combined with any load balancing solution. If a host is defined in the [Ib] section of the inventory file, Ansible installs and configures HAProxy automatically as the load balancing solution. If no host is defined, it is assumed you have pre-configured a load balancing solution of your choice to balance the master API (port 8443) on all master hosts.

For your pre-configured load balancing solution, you must have:

- A pre-created load balancer VIP configured for SSL passthrough.
- A domain name for VIP registered in DNS.
 - The domain name will become the value of both openshift_master_cluster_public_hostname and openshift_master_cluster_hostname in the OpenShift Container Platform installer.

See External Load Balancer Integrations for more information.

NOTE

For more on the high availability master architecture, see Kubernetes Infrastructure.

Note the following when using the native HA method:

- The advanced installation method does not currently support multiple HAProxy load balancers in an active-passive setup. See the Load Balancer Administration documentation for postinstallation amendments.
- In a HAProxy setup, controller manager servers run as standalone processes. They elect their active leader with a lease stored in etcd. The lease expires after 30 seconds by default. If a failure happens on an active controller server, it will take up to this number of seconds to elect another leader. The interval can be configured with the osm_controller_lease_ttl variable.

To configure multiple masters, refer to the following section.

Multiple Masters with Multiple etcd

The following describes an example environment for three masters, one HAProxy load balancer, three etcd hosts, and two nodes using the native HA method:

Host Name	Infrastructure Component to Install
master1.example.com	
master2.example.com	Master (clustered using native HA) and node
master3.example.com	
lb.example.com	HAProxy to load balance API master endpoints

Host Name	Infrastructure Component to Install
etcd1.example.com	
etcd2.example.com	etcd
etcd3.example.com	
node1.example.com	
node2.example.com	Node

NOTE

When specifying multiple **etcd** hosts, external **etcd** is installed and configured. Clustering of OpenShift Container Platform's embedded **etcd** is not supported.

You can see these example hosts present in the [masters], [etcd], [lb], and [nodes] sections of the following example inventory file:

Example 2.2. Multiple Masters Using HAProxy Inventory File

```
# Create an OSEv3 group that contains the master, nodes, etcd, and lb
groups.
# The 1b group lets Ansible configure HAProxy as the load balancing
# Comment 1b out if your load balancer is pre-configured.
[OSEv3:children]
masters
nodes
etcd
1b
# Set variables common for all OSEv3 hosts
[OSEv3:vars]
ansible_ssh_user=root
deployment_type=openshift-enterprise
# Uncomment the following to enable htpasswd authentication; defaults to
# DenyAllPasswordIdentityProvider.
#openshift_master_identity_providers=[{'name': 'htpasswd_auth', 'login':
'true', 'challenge': 'true', 'kind': 'HTPasswdPasswordIdentityProvider',
'filename': '/etc/origin/master/htpasswd'}]
# Native high availbility cluster method with optional load balancer.
# If no lb group is defined installer assumes that a load balancer has
# been preconfigured. For installation the value of
# openshift_master_cluster_hostname must resolve to the load balancer
# or to one or all of the masters defined in the inventory if no load
# balancer is present.
openshift_master_cluster_method=native
```

```
openshift_master_cluster_hostname=openshift-cluster.example.com
openshift_master_cluster_public_hostname=openshift-cluster.example.com
# apply updated node defaults
openshift_node_kubelet_args={'pods-per-core': ['10'], 'max-pods':
['250'], 'image-gc-high-threshold': ['90'], 'image-gc-low-threshold':
['80']}
# override the default controller lease ttl
#osm controller lease ttl=30
# enable ntp on masters to ensure proper failover
openshift_clock_enabled=true
# host group for masters
[masters]
master1.example.com
master2.example.com
master3.example.com
# host group for etcd
[etcd]
etcd1.example.com
etcd2.example.com
etcd3.example.com
# Specify load balancer host
[lb]
lb.example.com
# host group for nodes, includes region info
[nodes]
master[1:3].example.com
node1.example.com openshift_node_labels="{'region': 'primary', 'zone':
'east'}"
node2.example.com openshift_node_labels="{'region': 'primary', 'zone':
'west'}"
infra-node1.example.com openshift_node_labels="{'region': 'infra',
'zone': 'default'}"
infra-node2.example.com openshift_node_labels="{'region': 'infra',
'zone': 'default'}"
```

To use this example, modify the file to match your environment and specifications, and save it as /etc/ansible/hosts.

Multiple Masters with Master and etcd on the Same Host

The following describes an example environment for three masters with **etcd** on each host, one HAProxy load balancer, and two **nodes** using the **native** HA method:

Host Name	Infrastructure Component to Install
master1.example.com	

Host Name	Infrastructure Component to Installed node with etcd on each host
master2.example.com	
master3.example.com	
lb.example.com	HAProxy to load balance API master endpoints
node1.example.com	Node
node2.example.com	

You can see these example hosts present in the [masters], [etcd], [lb], and [nodes] sections of the following example inventory file:

```
# Create an OSEv3 group that contains the master, nodes, etcd, and 1b
# The 1b group lets Ansible configure HAProxy as the load balancing
solution.
# Comment lb out if your load balancer is pre-configured.
[OSEv3:children]
masters
nodes
etcd
1b
# Set variables common for all OSEv3 hosts
[OSEv3:vars]
ansible_ssh_user=root
deployment_type=openshift-enterprise
# Uncomment the following to enable htpasswd authentication; defaults to
# DenyAllPasswordIdentityProvider.
#openshift_master_identity_providers=[{'name': 'htpasswd_auth', 'login':
'true', 'challenge': 'true', 'kind': 'HTPasswdPasswordIdentityProvider',
'filename': '/etc/origin/master/htpasswd'}]
# Native high availability cluster method with optional load balancer.
# If no lb group is defined installer assumes that a load balancer has
# been preconfigured. For installation the value of
# openshift_master_cluster_hostname must resolve to the load balancer
# or to one or all of the masters defined in the inventory if no load
# balancer is present.
openshift_master_cluster_method=native
openshift_master_cluster_hostname=openshift-cluster.example.com
openshift_master_cluster_public_hostname=openshift-cluster.example.com
# override the default controller lease ttl
#osm_controller_lease_ttl=30
# host group for masters
[masters]
master1.example.com
```

```
master2.example.com
master3.example.com
# host group for etcd
[etcd]
master1.example.com
master2.example.com
master3.example.com
# Specify load balancer host
[lb]
lb.example.com
# host group for nodes, includes region info
[nodes]
master[1:3].example.com
node1.example.com openshift_node_labels="{'region': 'primary', 'zone':
'east'}"
node2.example.com openshift_node_labels="{'region': 'primary', 'zone':
'west'}"
infra-node1.example.com openshift_node_labels="{'region': 'infra', 'zone':
'default'}"
infra-node2.example.com openshift_node_labels="{'region': 'infra', 'zone':
'default'}"
```

To use this example, modify the file to match your environment and specifications, and save it as /etc/ansible/hosts.

2.6.5. Running the Advanced Installation

After you have configured Ansible by defining an inventory file in /etc/ansible/hosts, you run the advanced installation playbook via Ansible. OpenShift Container Platform installations are currently supported using the RPM-based installer, while the containerized installer is currently a Technology Preview feature.

2.6.5.1. Running the RPM-based Installer

The RPM-based installer uses Ansible installed via RPM packages to run playbooks and configuration files available on the local host. To run the installer, use the following command, specifying -i if your inventory file located somewhere other than /etc/ansible/hosts:

```
# ansible-playbook [-i /path/to/inventory] \
    /usr/share/ansible/openshift-ansible/playbooks/byo/config.yml
```

If for any reason the installation fails, before re-running the installer, see Known Issues to check for any specific instructions or workarounds.

2.6.5.2. Running the Containerized Installer

IMPORTANT

All system container components are Technology Preview features in OpenShift Container Platform 3.6. They must not be used in production and they are not supported for upgrades to OpenShift Container Platform 3.6. During this phase, they are only meant for use with new cluster installations in non-production environments.

The 3.5, the master now connects to etcd via IP address.

- + When configuring a cluster to use proxy settings (see Configuring Global Proxy Options), this change causes the master-to-etcd connection to be proxied as well, rather than being excluded by host name in each host's NO_PROXY setting (see Working with HTTP Proxies for more about NO_PROXY).
- + To workaround this issue, set the following:

+

```
openshift_no_proxy=https://<ip_address>:<port>
```

- + Use the IP that the master will use to contact the etcd cluster as the <ip_address>. The <port> should be 2379 if you are using standalone etcd (clustered) or 4001 for embedded etcd (single master, non-clustered etcd). The installer will be updated in a future release to handle this scenario automatically during installation and upgrades (BZ#1466783).
 - 1. Run the advanced installation using the following playbook:

```
# ansible-playbook /usr/share/ansible/openshift-
ansible/playbooks/byo/config.yml
```

If for any reason the installation fails, before re-running the installer, see Known Issues to check for any specific instructions or workarounds.

2. After the installation succeeds, continue to Verifying the Installation.

2.6.6. Verifying the Installation

oc get nodes

node2.example.com

After the installation completes:

1. Verify that the master is started and nodes are registered and reporting in **Ready** status. *On the master host*, run the following as root:

```
NAME STATUS AGE master.example.com Ready, SchedulingDisabled 165d node1.example.com Ready 165d
```

2. To verify that the web console is installed correctly, use the master host name and the web console port number to access the web console with a web browser.

Ready

For example, for a master host with a host name of master.openshift.com and using the default port of 8443, the web console would be found at

https://master.openshift.com:8443/console.

165d

3. Now that the install has been verified, run the following command on each master and node host to add the **atomic-openshift** packages back to the list of yum excludes on the host:

atomic-openshift-excluder exclude

NOTE

The default port for the console is 8443. If this was changed during the installation, the port can be found at openshift_master_console_port in the /etc/ansible/hosts file.

Verifying Multiple etcd Hosts

If you installed multiple etcd hosts:

1. First, verify that the etcd package, which provides the etcdctl command, is installed:

```
# yum install etcd
```

2. On a master host, verify the **etcd** cluster health, substituting for the FQDNs of your **etcd** hosts in the following:

3. Also verify the member list is correct:

```
# etcdctl -C \
https://etcd1.example.com:2379,https://etcd2.example.com:2379,https:
//etcd3.example.com:2379 \
    --ca-file=/etc/origin/master/master.etcd-ca.crt \
    --cert-file=/etc/origin/master/master.etcd-client.crt \
    --key-file=/etc/origin/master/master.etcd-client.key member list
```

Verifying Multiple Masters Using HAProxy

If you installed multiple masters using HAProxy as a load balancer, browse to the following URL according to your [Ib] section definition and check HAProxy's status:

```
http://<lb_hostname>:9000
```

You can verify your installation by consulting the HAProxy Configuration documentation.

2.6.7. Uninstalling OpenShift Container Platform

You can uninstall OpenShift Container Platform hosts in your cluster by running the *uninstall.yml* playbook. This playbook deletes OpenShift Container Platform content installed by Ansible, including:

Configuration

- Containers
- Default templates and image streams
- Images
- RPM packages

The playbook will delete content for any hosts defined in the inventory file that you specify when running the playbook. If you want to uninstall OpenShift Container Platform across all hosts in your cluster, run the playbook using the inventory file you used when installing OpenShift Container Platform initially or ran most recently:

```
# ansible-playbook [-i /path/to/file] \
    /usr/share/ansible/openshift-ansible/playbooks/adhoc/uninstall.yml
```

2.6.7.1. Uninstalling Nodes

You can also uninstall node components from specific hosts using the *uninstall.yml* playbook while leaving the remaining hosts and cluster alone:

WARNING

This method should only be used when attempting to uninstall specific node hosts and not for specific masters or etcd hosts, which would require further configuration changes within the cluster.

- 1. First follow the steps in Deleting Nodes to remove the node object from the cluster, then continue with the remaining steps in this procedure.
- 2. Create a different inventory file that only references those hosts. For example, to only delete content from one node:

```
[OSEv3:children]
nodes 1

[OSEv3:vars]
ansible_ssh_user=root
deployment_type=openshift-enterprise

[nodes]
node3.example.com openshift_node_labels="{'region': 'primary',
'zone': 'west'}" 2
```

- Only include the sections that pertain to the hosts you are interested in uninstalling.
- Only include hosts that you want to uninstall.
- 3. Specify that new inventory file using the -i option when running the uninstall.yml playbook:

ansible-playbook -i /path/to/new/file \
 /usr/share/ansible/openshiftansible/playbooks/adhoc/uninstall.yml

When the playbook completes, all OpenShift Container Platform content should be removed from any specified hosts.

2.6.8. Known Issues

- On failover in multiple master clusters, it is possible for the controller manager to overcorrect, which causes the system to run more pods than what was intended. However, this is a transient event and the system does correct itself over time. See https://github.com/kubernetes/kubernetes/issues/10030 for details.
- On failure of the Ansible installer, you must start from a clean operating system installation. If you are using virtual machines, start from a fresh image. If you are using bare metal machines, see Uninstalling OpenShift Container Platform for instructions.

2.6.9. What's Next?

Now that you have a working OpenShift Container Platform instance, you can:

- Configure authentication; by default, authentication is set to Deny All.
- Deploy an integrated Docker registry.
- Deploy a router.

2.7. DISCONNECTED INSTALLATION

2.7.1. Overview

Frequently, portions of a datacenter may not have access to the Internet, even via proxy servers. Installing OpenShift Container Platform in these environments is considered a disconnected installation.

An OpenShift Container Platform disconnected installation differs from a regular installation in two primary ways:

- The OpenShift Container Platform software channels and repositories are not available via Red Hat's content distribution network.
- OpenShift Container Platform uses several containerized components. Normally, these images are pulled directly from Red Hat's Docker registry. In a disconnected environment, this is not possible.

A disconnected installation ensures the OpenShift Container Platform software is made available to the relevant servers, then follows the same installation process as a standard connected installation. This topic additionally details how to manually download the container images and transport them onto the relevant servers.

Once installed, in order to use OpenShift Container Platform, you will need source code in a source control repository (for example, Git). This topic assumes that an internal Git repository is available that can host source code and this repository is accessible from the OpenShift Container Platform nodes.

Installing the source control repository is outside the scope of this document.

Also, when building applications in OpenShift Container Platform, your build may have some external dependencies, such as a Maven Repository or Gem files for Ruby applications. For this reason, and because they might require certain tags, many of the Quickstart templates offered by OpenShift Container Platform may not work on a disconnected environment. However, while Red Hat container images try to reach out to external repositories by default, you can configure OpenShift Container Platform to use your own internal repositories. For the purposes of this document, we assume that such internal repositories already exist and are accessible from the OpenShift Container Platform nodes hosts. Installing such repositories is outside the scope of this document.

NOTE

You can also have a Red Hat Satellite server that provides access to Red Hat content via an intranet or LAN. For environments with Satellite, you can synchronize the OpenShift Container Platform software onto the Satellite for use with the OpenShift Container Platform servers.

Red Hat Satellite 6.1 also introduces the ability to act as a Docker registry, and it can be used to host the OpenShift Container Platform containerized components. Doing so is outside of the scope of this document.

2.7.2. Prerequisites

This document assumes that you understand OpenShift Container Platform's overall architecture and that you have already planned out what the topology of your environment will look like.

2.7.3. Required Software and Components

In order to pull down the required software repositories and container images, you will need a Red Hat Enterprise Linux (RHEL) 7 server with access to the Internet and at least 100GB of additional free space. All steps in this section should be performed on the Internet-connected server as the root system user.

2.7.3.1. Syncing Repositories

Before you sync with the required repositories, you may need to import the appropriate GPG key:

```
# rpm --import /etc/pki/rpm-gpg/RPM-GPG-KEY-redhat-release
```

If the key is not imported, the indicated package is deleted after syncing the repository.

To sync the required repositories:

 Register the server with the Red Hat Customer Portal. You must use the login and password associated with the account that has access to the OpenShift Container Platform subscriptions:

```
# subscription-manager register
```

2. Attach to a subscription that provides OpenShift Container Platform channels. You can find the list of available subscriptions using:

```
# subscription-manager list --available --matches '*OpenShift*'
```

Then, find the pool ID for the subscription that provides OpenShift Container Platform, and attach it:

```
# subscription-manager attach --pool=<pool_id>
# subscription-manager repos --disable="*"
# subscription-manager repos \
    --enable="rhel-7-server-rpms" \
    --enable="rhel-7-server-extras-rpms" \
    --enable="rhel-7-fast-datapath-rpms" \
    --enable="rhel-7-server-ose-3.5-rpms"
```

3. The yum-utils command provides the reposync utility, which lets you mirror yum repositories, and createrepo can create a usable yum repository from a directory:

```
# yum -y install yum-utils createrepo docker git
```

You will need up to 110GB of free space in order to sync the software. Depending on how restrictive your organization's policies are, you could re-connect this server to the disconnected LAN and use it as the repository server. You could use USB-connected storage and transport the software to another server that will act as the repository server. This topic covers these options.

4. Make a path to where you want to sync the software (either locally or on your USB or other device):

```
# mkdir -p </path/to/repos>
```

5. Sync the packages and create the repository for each of them. You will need to modify the command for the appropriate path you created above:

```
# for repo in \
rhel-7-server-rpms \
rhel-7-server-extras-rpms \
rhel-7-fast-datapath-rpms \
rhel-7-server-ose-3.5-rpms
do
    reposync --gpgcheck -lm --repoid=${repo} --
download_path=/path/to/repos
    createrepo -v </path/to/repos/>${repo} -o </path/to/repos/>$done
```

2.7.3.2. Syncing Images

To sync the container images:

1. Start the Docker daemon:

```
# systemctl start docker
```

2. Pull all of the required OpenShift Container Platform containerized components. Replace <tag> with v3.5.5.31 for the latest version.

```
# docker pull registry.access.redhat.com/openshift3/ose-f5-router:
<tag>
```

```
# docker pull registry.access.redhat.com/openshift3/ose-deployer:
# docker pull registry.access.redhat.com/openshift3/ose:<tag>
# docker pull registry.access.redhat.com/openshift3/ose-egress-
router:<tag>
# docker pull registry.access.redhat.com/openshift3/ose-keepalived-
ipfailover:<tag>
# docker pull registry.access.redhat.com/openshift3/openvswitch:
# docker pull registry.access.redhat.com/openshift3/ose-recycler:
<taq>
# docker pull registry.access.redhat.com/openshift3/ose-docker-
builder:<tag>
# docker pull registry.access.redhat.com/openshift3/ose-docker-
registry:<tag>
# docker pull registry.access.redhat.com/openshift3/ose-haproxy-
router:<tag>
# docker pull registry.access.redhat.com/openshift3/node:<tag>
# docker pull registry.access.redhat.com/openshift3/ose-pod:<tag>
# docker pull registry.access.redhat.com/openshift3/ose-sti-builder:
<taq>
```

3. Pull all of the required OpenShift Container Platform containerized components for the additional centralized log aggregation and metrics aggregation components. Replace <tag> with v3.5 for the latest version.

```
# docker pull registry.access.redhat.com/openshift3/logging-curator:
<tag>
# docker pull registry.access.redhat.com/openshift3/logging-
elasticsearch:<tag>
# docker pull registry.access.redhat.com/openshift3/logging-kibana:
<tag>
# docker pull registry.access.redhat.com/openshift3/metrics-
deployer:<tag>
# docker pull registry.access.redhat.com/openshift3/metrics-
hawkular-openshift-agent:<tag>
# docker pull registry.access.redhat.com/openshift3/logging-auth-
proxy:<tag>
# docker pull registry.access.redhat.com/openshift3/logging-
deployer:<taq>
# docker pull registry.access.redhat.com/openshift3/logging-fluentd:
<tag>
# docker pull registry.access.redhat.com/openshift3/metrics-
cassandra:<tag>
# docker pull registry.access.redhat.com/openshift3/metrics-
hawkular-metrics:<tag>
# docker pull registry.access.redhat.com/openshift3/metrics-
heapster:<tag>
```

- 4. Pull the Red Hat-certified Source-to-Image (S2I) builder images that you intend to use in your OpenShift environment. You can pull the following images:
 - jboss-eap70-openshift
 - jboss-amq-62

- jboss-datagrid65-openshift
- jboss-decisionserver62-openshift
- jboss-eap64-openshift
- jboss-eap70-openshift
- jboss-webserver30-tomcat7-openshift
- jboss-webserver30-tomcat8-openshift
- mongodb
- mysql
- nodejs
- perl
- php
- postgresql
- python
- redhat-sso70-openshift
- ruby

Make sure to indicate the correct tag specifying the desired version number. For example, to pull both the previous and latest version of the Tomcat image:

```
# docker pull \
registry.access.redhat.com/jboss-webserver-3/webserver30-tomcat7-
openshift:latest
# docker pull \
registry.access.redhat.com/jboss-webserver-3/webserver30-tomcat7-
openshift:1.1
```

 If you are using a stand-alone registry or plan to enable the registry console with the integrated registry, you must pull the registry-console image.
 Replace <tag> with 3.5 for the latest version.

```
# docker pull registry.access.redhat.com/openshift3/registry-
console:<tag>
```

2.7.3.3. Preparing Images for Export

Container images can be exported from a system by first saving them to a tarball and then transporting them:

1. Make and change into a repository home directory:

```
# mkdir </path/to/repos/images>
# cd </path/to/repos/images>
```

2. Export the OpenShift Container Platform containerized components:

```
# docker save -o ose3-images.tar \
    registry.access.redhat.com/openshift3/ose-f5-router \
    registry.access.redhat.com/openshift3/ose-deployer \
    registry.access.redhat.com/openshift3/ose-egress-router \
    registry.access.redhat.com/openshift3/ose-keepalived-ipfailover

registry.access.redhat.com/openshift3/openvswitch \
    registry.access.redhat.com/openshift3/ose-recycler \
    registry.access.redhat.com/openshift3/ose-docker-builder \
    registry.access.redhat.com/openshift3/ose-docker-registry \
    registry.access.redhat.com/openshift3/ose-haproxy-router \
    registry.access.redhat.com/openshift3/ose-pod \
    registry.access.redhat.com/openshift3/ose-sti-builder \
    registry.access.redhat.com/openshift3/ose-sti-builder \
    registry.access.redhat.com/openshift3/ose-sti-builder \
    registry.access.redhat.com/openshift3/registry-console
```

3. If you synchronized the metrics and log aggregation images, export:

```
# docker save -o ose3-logging-metrics-images.tar \
    registry.access.redhat.com/openshift3/logging-curator:<tag>
    registry.access.redhat.com/openshift3/logging-elasticsearch:
<tag>
    registry.access.redhat.com/openshift3/logging-kibana:<tag>
    registry.access.redhat.com/openshift3/metrics-deployer:<tag>
    registry.access.redhat.com/openshift3/metrics-hawkular-
openshift-agent:<tag>
    registry.access.redhat.com/openshift3/logging-auth-proxy:<tag>
    registry.access.redhat.com/openshift3/logging-deployer:<tag>
    registry.access.redhat.com/openshift3/logging-fluentd:<tag>
    registry.access.redhat.com/openshift3/metrics-cassandra:<tag>
    registry.access.redhat.com/openshift3/metrics-hawkular-metrics:
<tag>
    registry.access.redhat.com/openshift3/metrics-heapster:<tag>
```

4. Export the S2I builder images that you synced in the previous section. For example, if you synced only the Jenkins and Tomcat images:

```
# docker save -o ose3-builder-images.tar \
    registry.access.redhat.com/jboss-webserver-3/webserver30-
tomcat7-openshift:latest \
    registry.access.redhat.com/jboss-webserver-3/webserver30-
tomcat7-openshift:1.1 \
    registry.access.redhat.com/openshift3/jenkins-1-rhe17 \
    registry.access.redhat.com/openshift3/jenkins-2-rhe17 \
    registry.access.redhat.com/openshift3/jenkins-slave-base-rhe17 \
    registry.access.redhat.com/openshift3/jenkins-slave-maven-rhe17 \
    registry.access.redhat.com/openshift3/jenkins-slave-nodejs-rhe17
```

2.7.4. Repository Server

During the installation (and for later updates, should you so choose), you will need a webserver to host

the repositories. RHEL 7 can provide the Apache webserver.

Option 1: Re-configuring as a Web server

If you can re-connect the server where you synchronized the software and images to your LAN, then you can simply install Apache on the server:

```
# yum install httpd
```

Skip to Placing the Software.

Option 2: Building a Repository Server

If you need to build a separate server to act as the repository server, install a new RHEL 7 system with at least 110GB of space. On this repository server during the installation, make sure you select the **Basic Web Server** option.

2.7.4.1. Placing the Software

1. If necessary, attach the external storage, and then copy the repository files into Apache's root folder. Note that the below copy step (cp -a) should be substituted with move (mv) if you are repurposing the server you used to sync:

```
# cp -a /path/to/repos /var/www/html/
# chmod -R +r /var/www/html/repos
# restorecon -vR /var/www/html
```

2. Add the firewall rules:

```
# firewall-cmd --permanent --add-service=http
# firewall-cmd --reload
```

3. Enable and start Apache for the changes to take effect:

```
# systemctl enable httpd
# systemctl start httpd
```

2.7.5. OpenShift Container Platform Systems

2.7.5.1. Building Your Hosts

At this point you can perform the initial creation of the hosts that will be part of the OpenShift Container Platform environment. It is recommended to use the latest version of RHEL 7 and to perform a minimal installation. You will also want to pay attention to the other OpenShift Container Platform-specific prerequisites.

Once the hosts are initially built, the repositories can be set up.

2.7.5.2. Connecting the Repositories

On all of the relevant systems that will need OpenShift Container Platform software components, create the required repository definitions. Place the following text in the /etc/yum.repos.d/ose.repo file, replacing <server_IP> with the IP or host name of the Apache server hosting the software

repositories:

```
[rhel-7-server-rpms]
name=rhel-7-server-rpms
baseurl=http://<server_IP>/repos/rhel-7-server-rpms
enabled=1
gpgcheck=0
[rhel-7-server-extras-rpms]
name=rhel-7-server-extras-rpms
baseurl=http://<server_IP>/repos/rhel-7-server-extras-rpms
enabled=1
gpgcheck=0
[rhel-7-fast-datapath-rpms]
name=rhel-7-fast-datapath-rpms
baseurl=http://<server_IP>/repos/rhel-7-fast-datapath-rpms
enabled=1
gpgcheck=0
[rhel-7-server-ose-3.5-rpms]
name=rhel-7-server-ose-3.5-rpms
baseurl=http://<server_IP>/repos/rhel-7-server-ose-3.5-rpms
enabled=1
gpgcheck=0
```

2.7.5.3. Host Preparation

At this point, the systems are ready to continue to be prepared following the OpenShift Container Platform documentation.

Skip the section titled Host Registration and start with Installing Base Packages.

2.7.6. Installing OpenShift Container Platform

2.7.6.1. Importing OpenShift Container Platform Containerized Components

To import the relevant components, securely copy the images from the connected host to the individual OpenShift Container Platform hosts:

```
# scp /var/www/html/repos/images/ose3-images.tar
root@<openshift_host_name>:
# ssh root@<openshift_host_name> "docker load -i ose3-images.tar"
```

If you prefer, you could use wget on each OpenShift Container Platform host to fetch the tar file, and then perform the Docker import command locally. Perform the same steps for the metrics and logging images, if you synchronized them.

On the host that will act as an OpenShift Container Platform master, copy and import the builder images:

```
# scp /var/www/html/images/ose3-builder-images.tar
root@<openshift_master_host_name>:
# ssh root@<openshift_master_host_name> "docker load -i ose3-builder-images.tar"
```

2.7.6.2. Running the OpenShift Container Platform Installer

You can now choose to follow the quick or advanced OpenShift Container Platform installation instructions in the documentation.

2.7.6.3. Creating the Internal Docker Registry

You now need to create the internal Docker registry.

If you want to install a stand-alone registry, you must pull the **registry-console** container image and set **deployment_subtype=registry** in the inventory file.

2.7.7. Post-Installation Changes

In one of the previous steps, the S2I images were imported into the Docker daemon running on one of the OpenShift Container Platform master hosts. In a connected installation, these images would be pulled from Red Hat's registry on demand. Since the Internet is not available to do this, the images must be made available in another Docker registry.

OpenShift Container Platform provides an internal registry for storing the images that are built as a result of the S2I process, but it can also be used to hold the S2I builder images. The following steps assume you did not customize the service IP subnet (172.30.0.0/16) or the Docker registry port (5000).

2.7.7.1. Re-tagging S2I Builder Images

1. On the master host where you imported the S2I builder images, obtain the service address of your Docker registry that you installed on the master:

```
# export REGISTRY=$(oc get service docker-registry -t
'{{.spec.clusterIP}}{{"\n"}}')
```

Next, tag all of the builder images that you synced and exported before pushing them into the OpenShift Container Platform Docker registry. For example, if you synced and exported only the Tomcat image:

```
# docker tag \
registry.access.redhat.com/jboss-webserver-3/webserver30-tomcat7-
openshift:1.1 \
$REGISTRY:5000/openshift/webserver30-tomcat7-openshift:1.1
# docker tag \
registry.access.redhat.com/jboss-webserver-3/webserver30-tomcat7-
openshift:latest \
$REGISTRY:5000/openshift/webserver30-tomcat7-openshift:1.2
# docker tag \
registry.access.redhat.com/jboss-webserver-3/webserver30-tomcat7-
openshift:latest \
$REGISTRY:5000/openshift/webserver30-tomcat7-openshift:latest
```

2.7.7.2. Configuring a Registry Location

If you are using an image registry other than the default at registry.access.redhat.com, specify the desired registry within the /etc/ansible/hosts file.

oreg_url=example.com/openshift3/ose-\${component}:\${version}
openshift_examples_modify_imagestreams=true

Depending on your registry, you may need to configure:

openshift_docker_additional_registries=example.com
oopenshift_docker_insecure_registries=example.com

Table 2.15. Registry Variables

Variable	Purpose
oreg_url	Set to the alternate image location. Necessary if you are not using the default registry at registry.access.redhat.com.
openshift_examples_modify_imagestrea ms	Set to true if pointing to a registry other than the default. Modifies the image stream location to the value of oreg_url .
<pre>openshift_docker_additional_registri es</pre>	openshift_docker_additional_registri es to add its value in theadd_registry line in /etc/sysconfig/docker. Withadd_registry, you can add your own registry to be used for Docker search and Docker pull. Use the add_registry option to list a set of registries, each prepended withadd-registry flag. The first registry added will be the first registry searched. For example, add_registry=add-registry registry.access.redhat.comadd- registry example.com.
openshift_docker_insecure_registries	Set openshift_docker_insecure_registries to add its value in the insecure_registry line in/etc/sysconfig/docker. If you have a registry secured with HTTPS but do not have proper certificates distributed, you can tell Docker not to look for full authorization by adding the registry to the insecure_registry line and uncommenting it. For example, insecure_registry— insecure-registry example.com.

2.7.7.3. Creating an Administrative User

Pushing the container images into OpenShift Container Platform's Docker registry requires a user with **cluster-admin** privileges. Because the default OpenShift Container Platform system administrator does not have a standard authorization token, they cannot be used to log in to the Docker registry.

To create an administrative user:

1. Create a new user account in the authentication system you are using with OpenShift Container Platform. For example, if you are using local htpasswd-based authentication:

```
# htpasswd -b /etc/openshift/openshift-passwd <admin_username>
<password>
```

2. The external authentication system now has a user account, but a user must log in to OpenShift Container Platform before an account is created in the internal database. Log in to OpenShift Container Platform for this account to be created. This assumes you are using the self-signed certificates generated by OpenShift Container Platform during the installation:

```
# oc login --certificate-authority=/etc/origin/master/ca.crt \
   -u <admin_username> https://<openshift_master_host>:8443
```

3. Get the user's authentication token:

```
# MYTOKEN=$(oc whoami -t)
# echo $MYTOKEN
iwo7hc4XilD2K0LL4V1055ExH2VlPmLD-W2-J0d6Fko
```

2.7.7.4. Modifying the Security Policies

1. Using **oc login** switches to the new user. Switch back to the OpenShift Container Platform system administrator in order to make policy changes:

```
# oc login -u system:admin
```

2. In order to push images into the OpenShift Container Platform Docker registry, an account must have the image-builder security role. Add this to your OpenShift Container Platform administrative user:

```
# oadm policy add-role-to-user system:image-builder <admin_username>
```

3. Next, add the administrative role to the user in the **openshift** project. This allows the administrative user to edit the **openshift** project, and, in this case, push the container images:

```
# oadm policy add-role-to-user admin <admin_username> -n openshift
```

2.7.7.5. Editing the Image Stream Definitions

The **openshift** project is where all of the image streams for builder images are created by the installer. They are loaded by the installer from the **/usr/share/openshift/examples** directory. Change all of the definitions by deleting the image streams which had been loaded into OpenShift Container Platform's database, then re-create them:

1. Delete the existing image streams:

```
# oc delete is -n openshift --all
```

Make a backup of the files in /usr/share/openshift/examples/if you desire. Next, edit the file image-streams-rhel7.json in the /usr/share/openshift/examples/image-streams folder. You will find an image stream section for each of the builder images. Edit the spec stanza to point

to your internal Docker registry. For example, change:

```
"spec": {
   "dockerImageRepository":
   "registry.access.redhat.com/rhscl/mongodb-26-rhel7",
```

to:

```
"spec": {
   "dockerImageRepository": "172.30.69.44:5000/openshift/mongodb-26-
rhel7",
```

In the above, the repository name was changed from **rhscl** to **openshift**. You will need to ensure the change, regardless of whether the repository is **rhscl**, **openshift3**, or another directory. Every definition should have the following format:

```
<registry_ip>:5000/openshift/<image_name>
```

Repeat this change for every image stream in the file. Ensure you use the correct IP address that you determined earlier. When you are finished, save and exit. Repeat the same process for the JBoss image streams in the /usr/share/openshift/examples/xpaas-streams/jboss-image-streams.json file.

3. Load the updated image stream definitions:

```
# oc create -f /usr/share/openshift/examples/image-streams/image-
streams-rhel7.json -n openshift
# oc create -f /usr/share/openshift/examples/xpaas-streams/jboss-
image-streams.json -n openshift
```

2.7.7.6. Loading the Container Images

At this point the system is ready to load the container images.

1. Log in to the Docker registry using the token and registry service IP obtained earlier:

```
# docker login -u adminuser -e mailto:adminuser@abc.com \
-p $MYTOKEN $REGISTRY:5000
```

2. Push the Docker images:

```
# docker push $REGISTRY:5000/openshift/webserver30-tomcat7-
openshift:1.1
# docker push $REGISTRY:5000/openshift/webserver30-tomcat7-
openshift:1.2
# docker push $REGISTRY:5000/openshift/webserver30-tomcat7-
openshift:latest
```

3. Verify that all the image streams now have the tags populated:

```
# oc get imagestreams -n openshift
NAME DOCKER REPO
```

```
TAGS

jboss-webserver30-tomcat7-openshift $REGISTRY/jboss-webserver-
3/webserver30-jboss-tomcat7-openshift 1.1,1.1-2,1.1-6 + 2 more...
2 weeks ago
...
```

2.7.8. Installing a Router

At this point, the OpenShift Container Platform environment is almost ready for use. It is likely that you will want to install and configure a router.

2.8. INSTALLING A STAND-ALONE DEPLOYMENT OF OPENSHIFT CONTAINER REGISTRY

2.8.1. About OpenShift Container Registry

OpenShift Container Platform is a fully-featured platform-as-a-service (PaaS) enterprise solution that includes an integrated container registry called OpenShift Container Registry (OCR). Alternatively, instead of deploying OpenShift Container Platform as a full PaaS environment for developers, you can install OCR as a stand-alone container registry to run on-premise or in the cloud.

When installing a stand-alone deployment of OCR, a cluster of masters and nodes is still installed, similar to a typical OpenShift Container Platform installation. Then, the container registry is deployed to run on the cluster. This stand-alone deployment option is useful for administrators that want a container registry, but do not require the full OpenShift Container Platform environment that includes the developer-focused web console and application build and deployment tools.

NOTE

OCR should not be confused with the upstream project Atomic Registry, which is a different implementation using a non-Kubernetes deployment method that leverages systemd and local configuration files to manage services.

OCR provides the following capabilities:

- A user-focused registry web console.
- Secured traffic by default, served via TLS.
- Global identity provider authentication.
- A project namespace model to enable teams to collaborate through role-based access control (RBAC) authorization.
- A Kubernetes-based cluster to manage services.
- An image abstraction called image streams to enhance image management.

Administrators may want to deploy a stand-alone OCR to manage a registry separately that supports multiple OpenShift Container Platform clusters. A stand-alone OCR also enables administrators to separate their registry to satisfy their own security or compliance requirements.

2.8.2. Minimum Hardware Requirements

Installing a stand-alone OCR has the following hardware requirements:

- Physical or virtual system, or an instance running on a public or private laaS.
- Base OS: RHEL 7.3 with the "Minimal" installation option and the latest packages from the RHEL 7 Extras channel, or RHEL Atomic Host 7.3.2 or later. RHEL 7.2 is also supported using Docker 1.12 and its dependencies.
- NetworkManager 1.0 or later
- 2 vCPU.
- Minimum 16 GB RAM.
- Minimum 15 GB hard disk space for the file system containing /var/.
- An additional minimum 15 GB unallocated space to be used for Docker's storage back end; see Configuring Docker Storage for details.

IMPORTANT

OpenShift Container Platform only supports servers with x86_64 architecture.

NOTE

Meeting the /var/ file system sizing requirements in RHEL Atomic Host requires making changes to the default configuration. See Managing Storage in Red Hat Enterprise Linux Atomic Host for instructions on configuring this during or after installation.

2.8.3. Supported System Topologies

The following system topologies are supported for stand-alone OCR:

All-in-one	A single host that includes the master, node, etcd, and registry components.
Multiple Masters (Highly- Available)	Three hosts with all components included on each (master, node, etcd, and registry), with the masters configured for native high-availability.

2.8.4. Host Preparation

Before installing stand-alone OCR, all of the same steps detailed in the Host Preparation topic for installing a full OpenShift Container Platform PaaS must be performed. This includes registering and subscribing the host(s) to the proper repositories, installing or updating certain packages, and setting up Docker and its storage requirements.

Follow the steps in the Host Preparation topic, then continue to Installation Methods.

2.8.5. Installation Methods

To install a stand-alone registry, use either of the standard installation methods (quick or advanced) used to install any variant of OpenShift Container Platform.

2.8.5.1. Quick Installation for Stand-alone OpenShift Container Registry

When using the quick installation method to install stand-alone OCR, start the interactive installation by running:

\$ atomic-openshift-installer install

Then follow the on-screen instructions to install a new registry. The installation questions will be largely the same as if you were installing a full OpenShift Container Platform PaaS, but when you reach the following screen:

Which variant would you like to install?

- (1) OpenShift Container Platform
- (2) Registry

Be sure to choose 2 to follow the registry installation path.

NOTE

For further usage details on the quick installer in general, see the full topic at Quick Installation.

2.8.5.2. Advanced Installation for Stand-alone OpenShift Container Registry

When using the advanced installation method to install stand-alone OCR, use the same steps for installing a full OpenShift Container Platform PaaS using Ansible described in the full Advanced Installation topic. The main difference is that you must set deployment_subtype=registry in the inventory file within the [OSEv3:vars] section for the playbooks to follow the registry installation path.

See the following example inventory files for the different supported system topologies:

All-in-one Stand-alone OpenShift Container Registry Inventory File

```
# Create an OSEv3 group that contains the masters and nodes groups
[OSEv3:children]
masters
nodes

# Set variables common for all OSEv3 hosts
[OSEv3:vars]
# SSH user, this user should allow ssh based auth without requiring a password
ansible_ssh_user=root

openshift_master_default_subdomain=apps.test.example.com

# If ansible_ssh_user is not root, ansible_become must be set to true
#ansible_become=true

deployment_type=openshift-enterprise
deployment_subtype=registry 1
```

- Set deployment_subtype=registry to ensure installation of stand-alone OCR and not a full OpenShift Container Platform environment.
- Set openshift_schedulable=true on the node entry to make the single node schedulable for pod placement.

Multiple Masters (Highly-Available) Stand-alone OpenShift Container Registry Inventory File

```
# Create an OSEv3 group that contains the master, nodes, etcd, and 1b
# The 1b group lets Ansible configure HAProxy as the load balancing
# Comment 1b out if your load balancer is pre-configured.
[OSEv3:children]
masters
nodes
etcd
1b
# Set variables common for all OSEv3 hosts
[OSEv3:vars]
ansible_ssh_user=root
deployment_type=openshift-enterprise
deployment_subtype=registry 1
openshift_master_default_subdomain=apps.test.example.com
# Uncomment the following to enable htpasswd authentication; defaults to
# DenyAllPasswordIdentityProvider.
#openshift_master_identity_providers=[{'name': 'htpasswd_auth', 'login':
'true', 'challenge': 'true', 'kind': 'HTPasswdPasswordIdentityProvider',
'filename': '/etc/origin/master/htpasswd'}]
# Native high availability cluster method with optional load balancer.
# If no lb group is defined installer assumes that a load balancer has
# been preconfigured. For installation the value of
# openshift_master_cluster_hostname must resolve to the load balancer
```

```
# or to one or all of the masters defined in the inventory if no load
# balancer is present.
openshift_master_cluster_method=native
openshift_master_cluster_hostname=openshift-cluster.example.com
openshift_master_cluster_public_hostname=openshift-cluster.example.com
# apply updated node defaults
openshift_node_kubelet_args={'pods-per-core': ['10'], 'max-pods': ['250'],
'image-gc-high-threshold': ['90'], 'image-gc-low-threshold': ['80']}
# override the default controller lease ttl
#osm controller lease ttl=30
# enable ntp on masters to ensure proper failover
openshift_clock_enabled=true
# host group for masters
[masters]
master1.example.com
master2.example.com
master3.example.com
# host group for etcd
[etcd]
etcd1.example.com
etcd2.example.com
etcd3.example.com
# Specify load balancer host
[lb]
lb.example.com
# host group for nodes, includes region info
[nodes]
master[1:3].example.com openshift_node_labels="{'region': 'infra', 'zone':
'default'}" openshift_schedulable=true
node1.example.com openshift_node_labels="{'region': 'primary', 'zone':
'east'}"
node2.example.com openshift_node_labels="{'region': 'primary', 'zone':
'west'}"
```

Set deployment_subtype=registry to ensure installation of stand-alone OCR and not a full OpenShift Container Platform environment.

After you have configured Ansible by defining an inventory file in /etc/ansible/hosts, you can run the advanced installation using the following playbook:

```
# ansible-playbook /usr/share/ansible/openshift-
ansible/playbooks/byo/config.yml
```

NOTE

For more detailed usage information on the advanced installation method, including a comprehensive list of available Ansible variables, see the full topic at Advanced Installation.

CHAPTER 3. SETTING UP THE REGISTRY

3.1. REGISTRY OVERVIEW

3.1.1. About the Registry

OpenShift Container Platform can build container images from your source code, deploy them, and manage their lifecycle. To enable this, OpenShift Container Platform provides an internal, integrated Docker registry that can be deployed in your OpenShift Container Platform environment to locally manage images.

3.1.2. Integrated or Stand-alone Registries

During an initial installation of a full OpenShift Container Platform cluster, it is likely that the registry was deployed automatically during the installation process. If it was not, or if you want to further customize the configuration of your registry, see Deploying a Registry on Existing Clusters.

While it can be deployed to run as an integrated part of your full OpenShift Container Platform cluster, the OpenShift Container Platform registry can alternatively be installed separately as a stand-alone container image registry.

To install a stand-alone registry, follow Installing a Stand-alone Registry. This installation path deploys an all-in-one cluster running a registry and specialized web console.

3.2. DEPLOYING A REGISTRY ON EXISTING CLUSTERS

3.2.1. Overview

If the integrated registry was not previously deployed automatically during the initial installation of your OpenShift Container Platform cluster, or if it is no longer running successfully and you need to redeploy it on your existing cluster, see the following sections for options on deploying a new registry.

NOTE

This topic is not required if you installed a stand-alone registry.

3.2.2. Deploying the Registry

To deploy the integrated Docker registry, use the **oadm registry** command as a user with cluster administrator privileges. For example:

```
$ oadm registry --config=/etc/origin/master/admin.kubeconfig \1
    --service-account=registry \2
    --images='registry.access.redhat.com/openshift3/ose-
${component}:${version}' 3
```

- --config is the path to the CLI configuration file for the cluster administrator.
- --service-account is the service account used to run the registry's pod.
- Required to pull the correct image for OpenShift Container Platform.

This creates a service and a deployment configuration, both called **docker-registry**. Once deployed successfully, a pod is created with a name similar to **docker-registry-1-cpty9**.

To see a full list of options that you can specify when creating the registry:

\$ oadm registry --help

3.2.3. Deploying the Registry as a DaemonSet

Use the **oadm** registry command to deploy the registry as a **DaemonSet** with the **--daemonset** option.

Daemonsets ensure that when nodes are created, they contain copies of a specified pod. When the nodes are removed, the pods are garbage collected.

For more information on DaemonSets, see Using Daemonsets.

3.2.4. Registry Compute Resources

By default, the registry is created with no settings for compute resource requests or limits. For production, it is highly recommended that the deployment configuration for the registry be updated to set resource requests and limits for the registry pod. Otherwise, the registry pod will be considered a BestEffort pod.

See Compute Resources for more information on configuring requests and limits.

3.2.5. Storage for the Registry

The registry stores container images and metadata. If you simply deploy a pod with the registry, it uses an ephemeral volume that is destroyed if the pod exits. Any images anyone has built or pushed into the registry would disappear.

This section lists the supported registry storage drivers.

The following list includes storage drivers that need to be configured in the registry's configuration file:

- Filesystem. Filesystem is the default and does not need to be configured.
- S3. Learn more about CloudFront configuration.
- OpenStack Swift
- Google Cloud Storage (GCS)
- Microsoft Azure
- Aliyun OSS

General registry storage configuration options are supported.

The following storage options need to be configured through the filesystem driver:

- Backing Docker Registry with GlusterFS Storage
- Ceph Rados Block Device

NOTE

For more information on supported persistent storage drivers, see Configuring Persistent Storage and Persistent Storage Examples.

3.2.5.1. Production Use

For production use, attach a remote volume or define and use the persistent storage method of your choice.

For example, to use an existing persistent volume claim:

NOTE

See Known Issues if using a scaled registry with a shared NFS volume.

3.2.5.1.1. Use Amazon S3 as a Storage Back-end

There is also an option to use Amazon Simple Storage Service storage with the internal Docker registry. It is a secure cloud storage manageable through AWS Management Console. To use it, the registry's configuration file must be manually edited and mounted to the registry pod. However, before you start with the configuration, look at upstream's recommended steps.

Take a default YAML configuration file as a base and replace the **filesystem** entry in the **storage** section with **s3** entry such as below. The resulting storage section may look like this:

```
storage:
  cache:
    layerinfo: inmemory
  delete:
    enabled: true
  s3:
    accesskey: awsaccesskey 1
    secretkey: awssecretkey 2
    region: us-west-1
    regionendpoint: http://myobjects.local
    bucket: bucketname
    encrypt: true
    keyid: mykeyid
    secure: true
    v4auth: false
    chunksize: 5242880
    rootdirectory: /s3/object/name/prefix
```

- Replace with your Amazon access key.
- 2 Replace with your Amazon secret key.

All of the s3 configuration options are documented in upstream's driver reference documentation.

Overriding the registry configuration will take you through the additional steps on mounting the configuration file into pod.

WARNING

When the registry runs on the S3 storage back-end, there are reported issues.

3.2.5.2. Non-Production Use

For non-production use, you can use the --mount-host=<path> option to specify a directory for the registry to use for persistent storage. The registry volume is then created as a host-mount at the specified <path>.

IMPORTANT

The --mount-host option mounts a directory from the node on which the registry container lives. If you scale up the **docker-registry** deployment configuration, it is possible that your registry pods and containers will run on different nodes, which can result in two or more registry containers, each with its own local storage. This will lead to unpredictable behavior, as subsequent requests to pull the same image repeatedly may not always succeed, depending on which container the request ultimately goes to.

The --mount-host option requires that the registry container run in privileged mode. This is automatically enabled when you specify --mount-host. However, not all pods are allowed to run privileged containers by default. If you still want to use this option, create the registry and specify that it use the registry service account that was created during installation:

```
$ oadm registry --service-account=registry \
    --config=/etc/origin/master/admin.kubeconfig \
    --images='registry.access.redhat.com/openshift3/ose-
${component}:${version}' \
    --mount-host=<path>
```

IMPORTANT

The Docker registry pod runs as user **1001**. This user must be able to write to the host directory. You may need to change directory ownership to user ID **1001** with this command:

\$ sudo chown 1001:root <path>

3.2.6. Enabling the Registry Console

OpenShift Container Platform provides a web-based interface to the integrated registry. This registry console is an optional component for browsing and managing images. It is deployed as a stateless service running as a pod.

NOTE

If you installed OpenShift Container Platform as a stand-alone registry, the registry console is already deployed and secured automatically during installation.

IMPORTANT

If Cockpit is already running, you'll need to shut it down before proceeding in order to avoid a port conflict (9090 by default) with the registry console.

3.2.6.1. Deploying the Registry Console

IMPORTANT

You must first have exposed the registry.

1. Create a passthrough route in the **default** project. You will need this when creating the registry console application in the next step.

```
$ oc create route passthrough --service registry-console \
    --port registry-console \
    -n default
```

2. Deploy the registry console application. Replace **<openshift_oauth_ur1>** with the URL of the OpenShift Container Platform OAuth provider, which is typically the master.

NOTE

If the redirection URL is wrong when you are trying to log in to the registry console, check your OAuth client with oc get oauthclients.

1. Finally, use a web browser to view the console using the route URI.

3.2.6.2. Securing the Registry Console

By default, the registry console generates self-signed TLS certificates if deployed manually per the steps in Deploying the Registry Console. See Troubleshooting the Registry Console for more information.

Use the following steps to add your organization's signed certificates as a secret volume. This assumes your certificates are available on the the oc client host.

- 1. Create a .cert file containing the certificate and key. Format the file with:
 - One or more BEGIN CERTIFICATE blocks for the server certificate and the intermediate

certificate authorities

• A block containing a **BEGIN PRIVATE KEY** or similar for the key. The key must not be encrypted

For example:

```
----BEGIN CERTIFICATE----
MIIDUZCCAjugAwIBAGIJAPXW+CUNYS6QMA0GCSqGSIb3DQEBCwUAMD8xKTAnBgNV
BAOMIGI00GE2NGNkNmMwNTQ1YThhZTgxOTEzZDE5YmJjMmRjMRIwEAYDVQQDDAls
...
----END CERTIFICATE----
MIIDUZCCAjugAwIBAGIJAPXW+CUNYS6QMA0GCSqGSIb3DQEBCwUAMD8xKTAnBgNV
BAOMIGI00GE2NGNkNmMwNTQ1YThhZTgxOTEzZDE5YmJjMmRjMRIwEAYDVQQDDAls
...
----END CERTIFICATE----
MIIEvgIBADANBgkqhkiG9w0BAQEFAASCBKgwggSkAgEAAoIBAQCy0J5gar0Yw0sm
8TBCDSqQ/H1awGMzDYdB11xuHHsxYS2VepPMzMzryHR137I4dGFLhvdTvJUH8lUS
...
----END PRIVATE KEY-----
```

The registry console loads a certificate from the /etc/cockpit/ws-certs.d directory. It uses the last file with a .cert extension in alphabetical order. Therefore, the .cert file should contain at least two PEM blocks formatted in the OpenSSL style.

If no certificate is found, a self-signed certificate is created using the **openss1** command and stored in the **0-self-signed.cert** file.

2. Create the secret:

```
$ oc secrets new console-secret \
    /path/to/console.cert
```

3. Add the secrets to the registry-console deployment configuration:

```
$ oc volume dc/registry-console --add --type=secret \
    --secret-name=console-secret -m /etc/cockpit/ws-certs.d
```

This triggers a new deployment of the registry console to include your signed certificates.

3.2.6.3. Troubleshooting the Registry Console

3.2.6.3.1. Debug Mode

The registry console debug mode is enabled using an environment variable. The following command redeploys the registry console in debug mode:

```
\$ oc set env dc registry-console <code>G_MESSAGES_DEBUG=cockpit-ws,cockpit-wrapper</code>
```

Enabling debug mode allows more verbose logging to appear in the registry console's pod logs.

3.2.6.3.2. Display SSL Certificate Path

To check which certificate the registry console is using, a command can be run from inside the console pod.

1. List the pods in the default project and find the registry console's pod name:

```
$ oc get pods -n default

NAME READY STATUS RESTARTS AGE
registry-console-1-rssrw 1/1 Running 0 1d
```

2. Using the pod name from the previous command, get the certificate path that the **cockpit-ws** process is using. This example shows the console using the auto-generated certificate:

```
$ oc exec registry-console-1-rssrw remotectl certificate
certificate: /etc/cockpit/ws-certs.d/0-self-signed.cert
```

3.3. ACCESSING THE REGISTRY

3.3.1. Viewing Logs

To view the logs for the Docker registry, use the **oc logs** command with the deployment configuration:

```
$ oc logs dc/docker-registry
2015-05-01T19:48:36.300593110Z time="2015-05-01T19:48:36Z" level=info
msg="version=v2.0.0+unknown"

msg="listening on :5000" instance.id=9ed6c43d-23ee-453f-9a4b-031fea646002
```

3.3.2. File Storage

Tag and image metadata is stored in OpenShift Container Platform, but the registry stores layer and signature data in a volume that is mounted into the registry container at /registry. As oc exec does not work on privileged containers, to view a registry's contents you must manually SSH into the node housing the registry pod's container, then run docker exec on the container itself:

1. List the current pods to find the pod name of your Docker registry:

```
# oc get pods
```

Then, use oc describe to find the host name for the node running the container:

```
# oc describe pod <pod_name>
```

2. Log into the desired node:

ssh node.example.com

3. List the running containers from the default project on the node host and identify the container ID for the Docker registry:

docker ps --filter=name=registry_docker-registry.*_default_

4. List the registry contents using the **oc rsh** command:

oc rsh dc/docker-registry find /registry /registry/docker /registry/docker/registry /registry/docker/registry/v2 /registry/docker/registry/v2/blobs 1 /registry/docker/registry/v2/blobs/sha256 /registry/docker/registry/v2/blobs/sha256/ed /registry/docker/registry/v2/blobs/sha256/ed/ede17b139a271d6b1331ca3 d83c648c24f92cece5f89d95ac6c34ce751111810 /registry/docker/registry/v2/blobs/sha256/ed/ede17b139a271d6b1331ca3 d83c648c24f92cece5f89d95ac6c34ce751111810/data 2 /registry/docker/registry/v2/blobs/sha256/a3 /registry/docker/registry/v2/blobs/sha256/a3/a3ed95caeb02ffe68cdd9fd 84406680ae93d633cb16422d00e8a7c22955b46d4 /registry/docker/registry/v2/blobs/sha256/a3/a3ed95caeb02ffe68cdd9fd 84406680ae93d633cb16422d00e8a7c22955b46d4/data /registry/docker/registry/v2/blobs/sha256/f7 /registry/docker/registry/v2/blobs/sha256/f7/f72a00a23f01987b42cb26f 259582bb33502bdb0fcf5011e03c60577c4284845 /registry/docker/registry/v2/blobs/sha256/f7/f72a00a23f01987b42cb26f 259582bb33502bdb0fcf5011e03c60577c4284845/data /registry/docker/registry/v2/repositories 3 /registry/docker/registry/v2/repositories/p1 /registry/docker/registry/v2/repositories/p1/pause 4 /registry/docker/registry/v2/repositories/p1/pause/_manifests /registry/docker/registry/v2/repositories/p1/pause/_manifests/revisi ons /registry/docker/registry/v2/repositories/p1/pause/_manifests/revisi ons/sha256 /registry/docker/registry/v2/repositories/p1/pause/_manifests/revisi ons/sha256/e9a2ac6418981897b399d3709f1b4a6d2723cd38a4909215ce2752a5c 068b1cf /registry/docker/registry/v2/repositories/p1/pause/_manifests/revisi ons/sha256/e9a2ac6418981897b399d3709f1b4a6d2723cd38a4909215ce2752a5c 068b1cf/signatures 5

- This directory stores all layers and signatures as blobs.
- This file contains the blob's contents.

9

- This directory stores all the image repositories.
- This directory is for a single image repository p1/pause.
- This directory contains signatures for a particular image manifest revision.
- This file contains a reference back to a blob (which contains the signature data).
- This directory contains any layers that are currently being uploaded and staged for the given repository.
- This directory contains links to all the layers this repository references.
- This file contains a reference to a specific layer that has been linked into this repository via an image.

3.3.3. Accessing the Registry Directly

For advanced usage, you can access the registry directly to invoke docker commands. This allows you to push images to or pull them from the integrated registry directly using operations like docker push or docker pull. To do so, you must be logged in to the registry using the docker login command. The operations you can perform depend on your user permissions, as described in the following sections.

3.3.3.1. User Prerequisites

To access the registry directly, the user that you use must satisfy the following, depending on your intended usage:

• For any direct access, you must have a regular user, if one does not already exist, for your preferred identity provider. A regular user can generate an access token required for logging in to the registry. System users, such as system:admin, cannot obtain access tokens and, therefore, cannot access the registry directly.

For example, if you are using **HTPASSWD** authentication, you can create one using the following command:

htpasswd /etc/origin/openshift-htpasswd <user_name>

• The user must have the system:registry role. To add this role:

```
# oadm policy add-role-to-user system:registry <user_name>
```

• Have the **admin** role for the project associated with the Docker operation. For example, if accessing images in the global **openshift** project:

```
$ oadm policy add-role-to-user admin <user_name> -n openshift
```

• For writing or pushing images, for example when using the **docker push** command, the user must have the **system:image-builder** role. To add this role:

```
$ oadm policy add-role-to-user system:image-builder <user_name>
```

For more information on user permissions, see Managing Role Bindings.

3.3.3.2. Logging in to the Registry

NOTE

Ensure your user satisfies the prerequisites for accessing the registry directly.

To log in to the registry directly:

1. Ensure you are logged in to OpenShift Container Platform as a regular user:

2. Log in to the Docker registry by using your access token:

```
docker login -u $(oc whoami) -p $(oc whoami -t) <registry_ip>:<port>
```

3.3.3. Pushing and Pulling Images

After logging in to the registry, you can perform docker pull and docker push operations against your registry.

IMPORTANT

You can pull arbitrary images, but if you have the **system:registry** role added, you can only push images to the registry in your project.

In the following examples, we use:

Component	Value
<registry_ip></registry_ip>	172.30.124.220

<port></port>	5000
<pre><pre><pre><pre><pre><pre><pre><pre></pre></pre></pre></pre></pre></pre></pre></pre>	openshift
<image/>	busybox
<tag></tag>	omitted (defaults to latest)

1. Pull an arbitrary image:

```
$ docker pull docker.io/busybox
```

2. Tag the new image with the form <registry_ip>:<port>//<image>. The project name must appear in this pull specification for OpenShift Container Platform to correctly place and later access the image in the registry.

```
$ docker tag docker.io/busybox 172.30.124.220:5000/openshift/busybox
```

NOTE

Your regular user must have the **system:image-builder** role for the specified project, which allows the user to write or push an image. Otherwise, the **docker push** in the next step will fail. To test, you can **create** a new project to push the **busybox** image.

3. Push the newly-tagged image to your registry:

```
$ docker push 172.30.124.220:5000/openshift/busybox
...
cf2616975b4a: Image successfully pushed
Digest:
sha256:3662dd821983bc4326bee12caec61367e7fb6f6a3ee547cbaff98f77403ca
b55
```

3.4. SECURING AND EXPOSING THE REGISTRY

3.4.1. Securing the Registry

Optionally, you can secure the registry so that it serves traffic via TLS:

- 1. Deploy the registry.
- 2. Fetch the service IP and port of the registry:

3. You can use an existing server certificate, or create a key and server certificate valid for specified IPs and host names, signed by a specified CA. To create a server certificate for the registry service IP and the docker-registry.default.svc.cluster.local host name:

```
$ oadm ca create-server-cert \
    --signer-cert=/etc/origin/master/ca.crt \
    --signer-key=/etc/origin/master/ca.key \
    --signer-serial=/etc/origin/master/ca.serial.txt \
    --hostnames='docker-
registry.default.svc.cluster.local,172.30.124.220' \
    --cert=/etc/secrets/registry.crt \
    --key=/etc/secrets/registry.key
```

If the router will be exposed externally, add the public route host name in the --hostnames flag:

```
--hostnames='mydocker-registry.example.com,docker-registry.default.svc.cluster.local,172.30.124.220
```

See Redeploying Registry and Router Certificates for additional details on updating the default certificate so that the route is externally accessible.

NOTE

The oadm ca create-server-cert command generates a certificate that is valid for two years. This can be altered with the --expire-days option, but for security reasons, it is recommended to not make it greater than this value.

4. Create the secret for the registry certificates:

```
$ oc secrets new registry-secret \
   /etc/secrets/registry.crt \
   /etc/secrets/registry.key
```

5. Add the secret to the registry pod's service accounts (including the default service account):

```
$ oc secrets link registry registry-secret
$ oc secrets link default registry-secret
```

NOTE

Limiting secrets to only the service accounts that reference them is disabled by default. This means that if

serviceAccountConfig.limitSecretReferences is set to **false** (the default setting) in the master configuration file, linking secrets to a service is not required.

6. Pause the docker-registry service:

```
$ oc rollout pause dc/docker-registry
```

7. Add the secret volume to the registry deployment configuration:

```
$ oc volume dc/docker-registry --add --type=secret \
    --secret-name=registry-secret -m /etc/secrets
```

8. Enable TLS by adding the following environment variables to the registry deployment configuration:

```
$ oc set env dc/docker-registry \
    REGISTRY_HTTP_TLS_CERTIFICATE=/etc/secrets/registry.crt \
    REGISTRY_HTTP_TLS_KEY=/etc/secrets/registry.key
```

See more details on overriding registry options.

9. Update the scheme used for the registry's liveness probe from HTTP to HTTPS:

10. If your registry was initially deployed on OpenShift Container Platform 3.2 or later, update the scheme used for the registry's readiness probe from HTTP to HTTPS:

11. Resume the docker-registry service:

```
$ oc rollout resume dc/docker-registry
```

12. Validate the registry is running in TLS mode. Wait until the latest **docker-registry** deployment completes and verify the Docker logs for the registry container. You should find an entry for **listening on :5000, tls.**

```
$ oc logs dc/docker-registry | grep tls
time="2015-05-27T05:05:53Z" level=info msg="listening on :5000, tls"
instance.id=deeba528-c478-41f5-b751-dc48e4935fc2
```

13. Copy the CA certificate to the Docker certificates directory. This must be done on all nodes in the cluster:

```
$ dcertsdir=/etc/docker/certs.d
$ destdir_addr=$dcertsdir/172.30.124.220:5000
$ destdir_name=$dcertsdir/docker-
registry.default.svc.cluster.local:5000

$ sudo mkdir -p $destdir_addr $destdir_name
$ sudo cp ca.crt $destdir_addr
$ sudo cp ca.crt $destdir_name
```

- 1
- The ca.crt file is a copy of /etc/origin/master/ca.crt on the master.
- 14. When using authentication, some versions of **docker** also require you to configure your cluster to trust the certificate at the OS level.
 - a. Copy the certificate:

```
$ cp /etc/origin/master/ca.crt /etc/pki/ca-
trust/source/anchors/myregistrydomain.com.crt
```

- b. Run:
 - \$ update-ca-trust enable
- 15. Remove the --insecure-registry option only for this particular registry in the /etc/sysconfig/docker file. Then, reload the daemon and restart the docker service to reflect this configuration change:

```
$ sudo systemctl daemon-reload
$ sudo systemctl restart docker
```

- 16. Validate the docker client connection. Running docker push to the registry or docker pull from the registry should succeed. Make sure you have logged into the registry.
 - \$ docker tag|push <registry/image> <internal_registry/project/image>

For example:

```
$ docker pull busybox
$ docker tag docker.io/busybox 172.30.124.220:5000/openshift/busybox
$ docker push 172.30.124.220:5000/openshift/busybox
...
cf2616975b4a: Image successfully pushed
Digest:
sha256:3662dd821983bc4326bee12caec61367e7fb6f6a3ee547cbaff98f77403ca
b55
```

3.4.2. Exposing the Registry

To expose your internal registry externally, it is recommended that you run a secure registry. To expose the registry you must first have deployed a router.

- 1. Deploy the registry.
- 2. Secure the registry.
- 3. Deploy a router.
- 4. Create a passthrough route via the oc create route passthrough command, specifying the registry as the route's service. By default, the name of the created route is the same as the service name.

For example:

```
$ oc get svc
NAME
                  CLUSTER_IP
                                   EXTERNAL_IP
                                                 PORT(S)
SELECTOR 
                          AGE
docker-registry 172.30.69.167
                                   <none>
                                                 5000/TCP
docker-registry=default
kubernetes
                  172.30.0.1
                                   <none>
443/TCP, 53/UDP, 53/TCP <none>
                                                  4h
router
                  172.30.172.132
                                                 80/TCP
                                   <none>
router=router
                          4h
$ oc create route passthrough
    --service=docker-registry
    --hostname=<host>
route "docker-registry" created
```

- Specify the registry as the route's service.
- The route name is identical to the service name.

```
$ oc get route/docker-registry -o yaml
apiVersion: v1
kind: Route
metadata:
   name: docker-registry
spec:
   host: <host> 1
   to:
     kind: Service
     name: docker-registry
2
tls:
   termination: passthrough 3
```

- The host for your route. You must be able to resolve this name externally via DNS to the router's IP address.
- The service name for your registry.
- Specify this route as a passthrough route.

NOTE

Passthrough is currently the only type of route supported for exposing the secure registry.

5. Next, you must trust the certificates being used for the registry on your host system. The certificates referenced were created when you secured your registry.

```
$ sudo mkdir -p /etc/docker/certs.d/<host>
$ sudo cp <ca certificate file> /etc/docker/certs.d/<host>
$ sudo systemctl restart docker
```

6. Log in to the registry using the information from securing the registry. However, this time point to the host name used in the route rather than your service IP. You should now be able to tag and push images using the route host.

```
$ oc get imagestreams -n test
NAME
          DOCKER REPO TAGS
                                  UPDATED
$ docker pull busybox
$ docker tag busybox <host>/test/busybox
$ docker push <host>/test/busybox
The push refers to a repository [<host>/test/busybox] (len: 1)
8c2e06607696: Image already exists
6ce2e90b0bc7: Image successfully pushed
cf2616975b4a: Image successfully pushed
Digest:
sha256:6c7e676d76921031532d7d9c0394d0da7c2906f4cb4c049904c4031147d8c
a31
$ docker pull <host>/test/busybox
latest: Pulling from <host>/test/busybox
cf2616975b4a: Already exists
6ce2e90b0bc7: Already exists
8c2e06607696: Already exists
Digest:
sha256:6c7e676d76921031532d7d9c0394d0da7c2906f4cb4c049904c4031147d8c
a31
Status: Image is up to date for <host>/test/busybox:latest
$ oc get imagestreams -n test
NAME
         DOCKER REPO
                                            TAGS
                                                      UPDATED
busybox
         172.30.11.215:5000/test/busybox
                                            latest
                                                      2 seconds ago
```

NOTE

Your image streams will have the IP address and port of the registry service, not the route name and port. See oc get imagestreams for details.

NOTE

In the <host>/test/busybox example above, test refers to the project name.

3.4.2.1. Exposing a Secure Registry

Instead of logging in to the registry from within the OpenShift Container Platform cluster, you can gain external access to it by first securing the registry and then exposing the registry. This allows you to log in to the registry from outside the cluster using the route address, and to tag and push images using the route host.

When logging in to the secured and exposed registry, make sure you specify the registry in the login command. For example:

docker login -e user@company.com -u f83j5h6 -p Ju1PeM47R0B92Lk3AZp-bWJSck2F7aGCiZ66aFGZrs2 registry.example.com:80

3.4.2.2. Exposing a Non-Secure Registry

Instead of securing the registry in order to expose the registry, you can simply expose a non-secure registry for non-production OpenShift Container Platform environments. This allows you to have an external route to the registry without using SSL certificates.

WARNING

Only non-production environments should expose a non-secure registry to external access.

To expose a non-secure registry:

1. Expose the registry:

```
# oc expose service docker-registry --hostname=<hostname> -n default
```

This creates the following JSON file:

```
apiVersion: v1
kind: Route
metadata:
    creationTimestamp: null
    labels:
        docker-registry: default
    name: docker-registry
spec:
    host: registry.example.com
    port:
        targetPort: "5000"
    to:
        kind: Service
        name: docker-registry
status: {}
```

2. Verify that the route has been created successfully:

```
# oc get route
NAME HOST/PORT PATH SERVICE
LABELS INSECURE POLICY TLS TERMINATION
docker-registry registry.example.com docker-registry
docker-registry=default
```

3. Check the health of the registry:

```
$ curl -v http://registry.example.com/healthz
```

Expect an HTTP 200/OK message.

After exposing the registry, update your /etc/sysconfig/docker file by adding the port number to the OPTIONS entry. For example:

OPTIONS='--selinux-enabled --insecure-registry=172.30.0.0/16 --insecure-registry registry.example.com:80'

IMPORTANT

The above options should be added on the client from which you are trying to log in.

Also, ensure that Docker is running on the client.

When logging in to the non-secured and exposed registry, make sure you specify the registry in the login command. For example:

docker login -e user@company.com -u f83j5h6 -p Ju1PeM47R0B92Lk3AZp-bWJSck2F7aGCiZ66aFGZrs2 registry.example.com:80

3.5. EXTENDED REGISTRY CONFIGURATION

3.5.1. Maintaining the Registry IP Address

OpenShift Container Platform refers to the integrated registry by its service IP address, so if you decide to delete and recreate the **docker-registry** service, you can ensure a completely transparent transition by arranging to re-use the old IP address in the new service. If a new IP address cannot be avoided, you can minimize cluster disruption by rebooting only the masters.

Re-using the Address

To re-use the IP address, you must save the IP address of the old **docker-registry** service prior to deleting it, and arrange to replace the newly assigned IP address with the saved one in the new **docker-registry** service.

1. Make a note of the clusterIP for the service:

```
$ oc get svc/docker-registry -o yaml | grep clusterIP:
```

2. Delete the service:

```
$ oc delete svc/docker-registry dc/docker-registry
```

Create the registry definition in registry.yaml, replacing <options> with, for example, those used in step 3 of the instructions in the Non-Production Use section:

```
$ oadm registry <options> -o yaml > registry.yaml
```

- 4. Edit *registry.yaml*, find the **Service** there, and change its **clusterIP** to the address noted in step 1.
- 5. Create the registry using the modified *registry.yaml*:

\$ oc create -f registry.yaml

Rebooting the Masters

If you are unable to re-use the IP address, any operation that uses a pull specification that includes the old IP address will fail. To minimize cluster disruption, you must reboot the masters:

systemctl restart atomic-openshift-master

This ensures that the old registry URL, which includes the old IP address, is cleared from the cache.

NOTE

We recommend against rebooting the entire cluster because that incurs unnecessary downtime for pods and does not actually clear the cache.

3.5.2. Whitelisting Docker Registries

You can specify a whitelist of docker registries, allowing you to curate a set of images and templates that are available for download by OpenShift Container Platform users. This curated set can be placed in one or more docker registries, and then added to the whitelist. When using a whitelist, only the specified registries are accessible within OpenShift Container Platform, and all other registries are denied access by default.

To configure a whitelist:

1. Edit the /etc/sysconfig/docker file to block all registries:

```
BLOCK_REGISTRY='--block-registry=all'
```

You may need to uncomment the BLOCK_REGISTRY line.

2. In the same file, add registries to which you want to allow access:

```
ADD_REGISTRY='--add-registry=<registry1> --add-registry=<registry2>'
```

Allowing Access to Registries

```
ADD_REGISTRY='--add-registry=registry.access.redhat.com'
```

This example would restrict access to images available on the Red Hat Customer Portal.

Once the whitelist is configured, if a user tries to pull from a docker registry that is not on the whitelist, they will receive an error message stating that this registry is not allowed.

3.5.3. Overriding the Registry Configuration

You can override the integrated registry's default configuration, found by default at /config.yml in a running registry's container, with your own custom configuration.

NOTE

Upstream configuration options in this file may also be overridden using environment variables. The middleware section is an exception as there are just a few options that can be overridden using environment variables. Learn how to override specific configuration options.

To enable management of the registry configuration file directly and deploy an updated configuration using a **ConfigMap**:

- 1. Deploy the registry.
- 2. Edit the registry configuration file locally as needed. The initial YAML file deployed on the registry is provided below. Review supported options.

Registry Configuration File

```
version: 0.1
log:
  level: debug
http:
  addr: :5000
storage:
  cache:
    blobdescriptor: inmemory
  filesystem:
    rootdirectory: /registry
  delete:
    enabled: true
auth:
  openshift:
    realm: openshift
middleware:
  registry:
    - name: openshift
  repository:
    - name: openshift
      options:
        acceptschema2: false
        pullthrough: true
        enforcequota: false
        projectcachettl: 1m
        blobrepositorycachettl: 10m
  storage:
    - name: openshift
```

3. Create a **ConfigMap** holding the content of each file in this directory:

```
$ oc create configmap registry-config \
    --from-file=</path/to/custom/registry/config.yml>/
```

4. Add the **registry-config** ConfigMap as a volume to the registry's deployment configuration to mount the custom configuration file at **/etc/docker/registry/**:

```
$ oc volume dc/docker-registry --add --type=configmap \
    --configmap-name=registry-config -m /etc/docker/registry/
```

5. Update the registry to reference the configuration path from the previous step by adding the following environment variable to the registry's deployment configuration:

```
$ oc set env dc/docker-registry \
    REGISTRY_CONFIGURATION_PATH=/etc/docker/registry/config.yml
```

This may be performed as an iterative process to achieve the desired configuration. For example, during troubleshooting, the configuration may be temporarily updated to put it in **debug** mode.

To update an existing configuration:

WARNING

This procedure will overwrite the currently deployed registry configuration.

- 1. Edit the local registry configuration file, *config.yml*.
- 2. Delete the registry-config secret:

```
$ oc delete secret registry-config
```

3. Recreate the secret to reference the updated configuration file:

```
$ oc secrets new registry-config config.yml=
</path/to/custom/registry/config.yml>
```

4. Redeploy the registry to read the updated configuration:

```
$ oc rollout latest docker-registry
```

TIP

Maintain configuration files in a source control repository.

3.5.4. Registry Configuration Reference

There are many configuration options available in the upstream docker distribution library. Not all configuration options are supported or enabled. Use this section as a reference when overriding the registry configuration.

NOTE

Upstream configuration options in this file may also be overridden using environment variables. However, the middleware section may **not** be overridden using environment variables. Learn how to override specific configuration options.

3.5.4.1. Log

Upstream options are supported.

Example:

```
log:
  level: debug
  formatter: text
  fields:
    service: registry
    environment: staging
```

3.5.4.2. Hooks

Mail hooks are not supported.

3.5.4.3. Storage

This section lists the supported registry storage drivers.

The following list includes storage drivers that need to be configured in the registry's configuration file:

- Filesystem. Filesystem is the default and does not need to be configured.
- S3. Learn more about CloudFront configuration.
- OpenStack Swift
- Google Cloud Storage (GCS)
- Microsoft Azure
- Aliyun OSS

General registry storage configuration options are supported.

The following storage options need to be configured through the filesystem driver:

- Backing Docker Registry with GlusterFS Storage
- Ceph Rados Block Device

NOTE

For more information on supported persistent storage drivers, see Configuring Persistent Storage and Persistent Storage Examples.

General Storage Configuration Options

```
storage:
   delete:
    enabled: true 1
   redirect:
```

```
disable: false
cache:
blobdescriptor: inmemory
maintenance:
uploadpurging:
enabled: true
age: 168h
interval: 24h
dryrun: false
readonly:
enabled: false
```

This entry is **mandatory** for image pruning to work properly.

3.5.4.4. Auth

Auth options should not be altered. The openshift extension is the only supported option.

```
auth:
openshift:
realm: openshift
```

3.5.4.5. Middleware

The **repository** middleware extension allows to configure OpenShift Container Platform middleware responsible for interaction with OpenShift Container Platform and image proxying.

```
middleware:
   registry:
        - name: openshift 1
   repository:
        - name: openshift 2
        options:
            acceptschema2: false 3
            pullthrough: true 4
            mirrorpullthrough: true 5
            enforcequota: false 6
            projectcachettl: 1m 7
            blobrepositorycachettl: 10m 8
        storage:
        - name: openshift 9
```

- 129 These entries are mandatory. Their presence ensures required components are loaded. These values should not be changed.
- Allows you to store manifest schema v2 during a push to the registry. See below for more details.
- Allows the registry to act as a proxy for remote blobs. See below for more details.
- Allows the registry cache blobs to be served from remote registries for fast access later. The mirroring starts when the blob is accessed for the first time. The option has no effect if the pullthrough is disabled.

- Prevents blob uploads exceeding the size limit, which are defined in the targeted project.
- An expiration timeout for limits cached in the registry. The lower the value, the less time it takes for the limit changes to propagate to the registry. However, the registry will query limits from the server more frequently and, as a consequence, pushes will be slower.
- An expiration timeout for remembered associations between blob and repository. The higher the value, the higher probability of fast lookup and more efficient registry operation. On the other hand, memory usage will raise as well as a risk of serving image layer to user, who is no longer authorized to access it.

3.5.4.5.1. CloudFront Middleware

The CloudFront middleware extension can be added to support AWS, CloudFront CDN storage provider. CloudFront middleware speeds up distribution of image content internationally. The blobs are distributed to several edge locations around the world. The client is always directed to the edge with the lowest latency.

NOTE

The **CloudFront** middleware extension can be only used with S3 storage. It is utilized only during blob serving. Therefore, only blob downloads can be speeded up, not uploads.

The following is an example of minimal configuration of S3 storage driver with a CloudFront middleware:

```
version: 0.1
log:
  level: debug
http:
  addr: :5000
storage:
  cache:
    blobdescriptor: inmemory
  delete:
    enabled: true
  s3: 1
    accesskey: BJKMSZBRESWJQXRWMAEQ
    secretkey: 5ah5I91SNXbeoUXXDasFtadRqOdy62JzlnOW1goS
    region: us-east-1
    bucket: docker.myregistry.com
auth:
  openshift:
    realm: openshift
middleware:
  registry:
    - name: openshift
  repository:
    - name: openshift
   storage:
    - name: cloudfront 2
      options:
        baseurl: https://jrpbyn0k5k88bi.cloudfront.net/ 3
```

privatekey: /etc/docker/cloudfront-ABCEDFGHIJKLMNOPQRST.pem 4
keypairid: ABCEDFGHIJKLMNOPQRST 5
- name: openshift

- The S3 storage must be configured the same way regardless of CloudFront middleware.
- The CloudFront storage middleware needs to be listed before OpenShift middleware.
- The CloudFront base URL. In the AWS management console, this is listed as **Domain Name** of CloudFront distribution.
- The location of your AWS private key on the filesystem. This must be not confused with Amazon EC2 key pair. Please refer to AWS documentation on creating CloudFront key pairs for your trusted signers. The file needs to be mounted as a secret secret into the registry pod.
- The ID of your Cloudfront key pair.

3.5.4.5.2. Overriding Middleware Configuration Options

The **middleware** section cannot be overridden using environment variables. There are a few exceptions, however. For example:

```
middleware:
  repository:
    - name: openshift
    options:
        acceptschema2: false 1
        pullthrough: true 2
        mirrorpullthrough: true 3
        enforcequota: false 4
        projectcachettl: 1m 5
        blobrepositorycachettl: 10m 6
```

- A configuration option that can be overridden by the boolean environment variable REGISTRY_MIDDLEWARE_REPOSITORY_OPENSHIFT_ACCEPTSCHEMA2, which allows for the ability to accept manifest schema v2 on manifest put requests. Recognized values are true and false (which applies to all the other boolean variables below).
- A configuration option that can be overridden by the boolean environment variable REGISTRY_MIDDLEWARE_REPOSITORY_OPENSHIFT_PULLTHROUGH, which enables a proxy mode for remote repositories.
- A configuration option that can be overridden by the boolean environment variable REGISTRY_MIDDLEWARE_REPOSITORY_OPENSHIFT_MIRRORPULLTHROUGH, which instructs registry to mirror blobs locally if serving remote blobs.
- A configuration option that can be overridden by the boolean environment variable REGISTRY_MIDDLEWARE_REPOSITORY_OPENSHIFT_ENFORCEQUOTA, which allows the ability to turn quota enforcement on or off. By default, quota enforcement is off.
- A configuration option that can be overridden by the environment variable REGISTRY_MIDDLEWARE_REPOSITORY_OPENSHIFT_PROJECTCACHETTL, specifying an eviction timeout for project quota objects. It takes a valid time duration string (for example, 2m). If empty,

you get the default timeout. If zero (0m), caching is disabled.

A configuration option that can be overridden by the environment variable REGISTRY_MIDDLEWARE_REPOSITORY_OPENSHIFT_BLOBREPOSITORYCACHETTL, specifying an eviction timeout for associations between blob and containing repository. The format of the value is the same as in projectcachettl case.

3.5.4.5.3. Image Pullthrough

If enabled, the registry will attempt to fetch requested blob from a remote registry unless the blob exists locally. The remote candidates are calculated from **DockerImage** entries stored in status of the image stream, a client pulls from. All the unique remote registry references in such entries will be tried in turn until the blob is found. The blob, served this way, will not be stored in the registry.

This feature is on by default. However, it can be disabled using a configuration option.

By default, all the remote blobs served this way are stored locally for subsequent faster access unless mirrorpullthrough is disabled. The downside of this mirroring feature is an increased storage usage.

NOTE

The mirroring starts when a client tries to fetch at least a single byte of the blob. To prefetch a particular image into integrated registry before it is actually needed, you can run the following command:

```
$ oc get imagestreamtag/${IS}:${TAG} -o jsonpath='{
.image.dockerImageLayers[*].name }' | \
    xargs -n1 -I {} curl -H "Range: bytes=0-1" -u user:${TOKEN} \
    http://${REGISTRY_IP}:${PORT}/v2/default/mysql/blobs/{}
```

3.5.4.5.4. Manifest Schema v2 Support

Each image has a manifest describing its blobs, instructions for running it and additional metadata. The manifest is versioned, with each version having different structure and fields as it evolves over time. The same image can be represented by multiple manifest versions. Each version will have different digest though.

The registry currently supports manifest v2 schema 1 (schema1) and manifest v2 schema 2 (schema2). The former is being obsoleted but will be supported for an extended amount of time.

You should be wary of compatibility issues with various Docker clients:

- Docker clients of version 1.9 or older support only **schema1**. Any manifest this client pulls or pushes will be of this legacy schema.
- Docker clients of version 1.10 support both **schema1** and **schema2**. And by default, it will push the latter to the registry if it supports newer schema.

The registry, storing an image with **schema1** will always return it unchanged to the client. **Schema2** will be transferred unchanged only to newer Docker client. For the older one, it will be converted onthe-fly to **schema1**.

This has significant consequences. For example an image pushed to the registry by a newer Docker client cannot be pulled by the older Docker by its digest. That's because the stored image's manifest is of **schema2** and its digest can be used to pull only this version of manifest.

For this reason, the registry is configured by default not to store **schema2**. This ensures that any docker client will be able to pull from the registry any image pushed there regardless of client's version.

Once you're confident that all the registry clients support **schema2**, you'll be safe to enable its support in the registry. See the middleware configuration reference above for particular option.

3.5.4.6. Reporting

Reporting is unsupported.

3.5.4.7. HTTP

Upstream options are supported. Learn how to alter these settings via environment variables . Only the tls section should be altered. For example:

```
http:
   addr: :5000
   tls:
     certificate: /etc/secrets/registry.crt
   key: /etc/secrets/registry.key
```

3.5.4.8. Notifications

Upstream options are supported. The REST API Reference provides more comprehensive integration options.

Example:

```
notifications:
    endpoints:
    - name: registry
    disabled: false
    url: https://url:port/path
    headers:
        Accept:
        - text/plain
    timeout: 500
    threshold: 5
    backoff: 1000
```

3.5.4.9. Redis

Redis is not supported.

3.5.4.10. Health

Upstream options are supported. The registry deployment configuration provides an integrated health check at /healthz.

3.5.4.11. Proxy

Proxy configuration should not be enabled. This functionality is provided by the OpenShift Container Platform repository middleware extension, pullthrough: true.

3.6. KNOWN ISSUES

3.6.1. Overview

The following are the known issues when deploying or using the integrated registry.

3.6.2. Image Push Errors with Scaled Registry Using Shared NFS Volume

When using a scaled registry with a shared NFS volume, you may see one of the following errors during the push of an image:

- digest invalid: provided digest did not match uploaded content
- blob upload unknown
- blob upload invalid

These errors are returned by an internal registry service when Docker attempts to push the image. Its cause originates in the synchronization of file attributes across nodes. Factors such as NFS client side caching, network latency, and layer size can all contribute to potential errors that might occur when pushing an image using the default round-robin load balancing configuration.

You can perform the following steps to minimize the probability of such a failure:

1. Ensure that the sessionAffinity of your docker-registry service is set to ClientIP:

```
$ oc get svc/docker-registry --template='{{.spec.sessionAffinity}}'
```

This should return **ClientIP**, which is the default in recent OpenShift Container Platform versions. If not, change it:

```
$ oc patch svc/docker-registry -p '{"spec":{"sessionAffinity":
"ClientIP"}}'
```

2. Ensure that the NFS export line of your registry volume on your NFS server has the no_wdelay options listed. The no_wdelay option prevents the server from delaying writes, which greatly improves read-after-write consistency, a requirement of the registry.

NOTE

The guidelines for NFS are recommended to help you get started. You may switch off from NFS when moving to production.

3.6.3. Pull of Internally Managed Image Fails with "not found" Error

This error occurs when the pulled image is pushed to an image stream different from the one it is being pulled from. This is caused by re-tagging a built image into an arbitrary image stream:

\$ oc tag srcimagestream:latest anyproject/pullimagestream:latest

And subsequently pulling from it, using an image reference such as:

internal.registry.url:5000/anyproject/pullimagestream:latest

During a manual Docker pull, this will produce a similar error:

Error: image anyproject/pullimagestream:latest not found

To prevent this, avoid the tagging of internally managed images completely, or re-push the built image to the desired namespace manually.

3.6.4. Image Push Fails with "500 Internal Server Error" on S3 Storage

There are problems reported happening when the registry runs on S3 storage back-end. Pushing to a Docker registry occasionally fails with the following error:

Received unexpected HTTP status: 500 Internal Server Error

To debug this, you need to view the registry logs. In there, look for similar error messages occurring at the time of the failed push:

```
time="2016-03-30T15:01:21.22287816-04:00" level=error msg="unknown error completing upload: driver.Error{DriverName:\"s3\", Enclosed:(*url.Error) (0xc20901cea0)}" http.request.method=PUT ...

time="2016-03-30T15:01:21.493067808-04:00" level=error msg="response completed with error" err.code=UNKNOWN err.detail="s3: Put https://s3.amazonaws.com/oso-tsi-docker/registry/docker/registry/v2/blobs/sha256/ab/abe5af443833d60cf672e2a c57589410dddec060ed725d3e676f1865af63d2e2/data: EOF" err.message="unknown error" http.request.method=PUT ...

time="2016-04-02T07:01:46.056520049-04:00" level=error msg="error putting into main store: s3: The request signature we calculated does not match the signature you provided. Check your key and signing method." http.request.method=PUT atest
```

If you see such errors, contact your Amazon S3 support. There may be a problem in your region or with your particular bucket.

3.6.5. Image Pruning Fails

If you encounter the following error when pruning images:

```
BLOB
```

sha256:49638d540b2b62f3b01c388e9d8134c55493b1fa659ed84e97cb59b87a6b8e6c error deleting blob

And your registry log contains the following information:

error deleting blob

\"sha256:49638d540b2b62f3b01c388e9d8134c55493b1fa659ed84e97cb59b87a6b8e6c\

": operation unsupported

It means that your custom configuration file lacks mandatory entries in the storage section, namely storage: delete: enabled set to true. Add them, re-deploy the registry, and repeat your image pruning operation.

CHAPTER 4. SETTING UP A ROUTER

4.1. ROUTER OVERVIEW

4.1.1. About Routers

There are many ways to get traffic into the cluster. The most common approach is to use the OpenShift Container Platform router as the ingress point for external traffic destined for services in your OpenShift Container Platform installation.

OpenShift Container Platform provides and supports the following router plug-ins:

- The HAProxy template router is the default plug-in. It uses the openshift3/ose-haproxy-router image to run an HAProxy instance alongside the template router plug-in inside a container on OpenShift Container Platform. It currently supports HTTP(S) traffic and TLS-enabled traffic via SNI. The router's container listens on the host network interface, unlike most containers that listen only on private IPs. The router proxies external requests for route names to the IPs of actual pods identified by the service associated with the route.
- The F5 router integrates with an existing F5 BIG-IP® system in your environment to synchronize routes. F5 BIG-IP® version 11.4 or newer is required in order to have the F5 iControl REST API.

NOTE

The F5 router plug-in is available starting in OpenShift Container Platform 3.0.2.

- Deploying a Default HAProxy Router
- Deploying a Custom HAProxy Router
- Deploying a F5 BIG-IP® Router
- Configuring the HAProxy Router to Use PROXY Protocol
- Configuring Route Timeouts

4.1.2. Router Service Account

Before deploying an OpenShift Container Platform cluster, you must have a service account for the router. Starting in OpenShift Container Platform 3.1, a router service account is automatically created during a quick or advanced installation (previously, this required manual creation). This service account has permissions to a security context constraint (SCC) that allows it to specify host ports.

4.1.2.1. Permission to Access Labels

When namespace labels are used, for example in creating router shards, the service account for the router must have cluster-reader permission.

```
$ oadm policy add-cluster-role-to-user \
    cluster-reader \
    system:serviceaccount:default:router
```

With a service account in place, you can proceed to installing a default HAProxy Router, a customized HAProxy Router or F5 Router.

4.2. USING THE DEFAULT HAPROXY ROUTER

4.2.1. Overview

The oc adm router command is provided with the administrator CLI to simplify the tasks of setting up routers in a new installation. If you followed the quick installation, then a default router was automatically created for you. The oc adm router command creates the service and deployment configuration objects. Use the --service-account option to specify the service account the router will use to contact the master.

The router service account can be created in advance or created by the oc adm router -- service-account command.

Every form of communication between OpenShift Container Platform components is secured by TLS and uses various certificates and authentication methods. The --default-certificate.pem format file can be supplied or one is created by the oc adm router command. When routes are created, the user can provide route certificates that the router will use when handling the route.

IMPORTANT

When deleting a router, ensure the deployment configuration, service, and secret are deleted as well.

Routers are deployed on specific nodes. This makes it easier for the cluster administrator and external network manager to coordinate which IP address will run a router and which traffic the router will handle. The routers are deployed on specific nodes by using node selectors.

IMPORTANT

Routers use host networking by default, and they directly attach to port 80 and 443 on all interfaces on a host. Restrict routers to hosts where ports 80/443 are available and not being consumed by another service, and set this using node selectors and the scheduler configuration. As an example, you can achieve this by dedicating infrastructure nodes to run services such as routers.

IMPORTANT

It is recommended to use separate distinct **openshift-router** service account with your router. This can be provided using the **--service-account** flag to the **oadm router** command.

IMPORTANT

Router pods created using oadm router have default resource requests that a node must satisfy for the router pod to be deployed. In an effort to increase the reliability of infrastructure components, the default resource requests are used to increase the QoS tier of the router pods above pods without resource requests. The default values represent the observed minimum resources required for a basic router to be deployed and can be edited in the routers deployment configuration and you may want to increase them based on the load of the router.

4.2.2. Creating a Router

The quick installation process automatically creates a default router. If the router does not exist, run the following to create a router:

```
$ oadm router <router_name> --replicas=<number> --service-account=router
```

--replicas is usually 1 unless a high availability configuration is being created.

To find the host IP address of the router:

```
$ oc get po <router-pod> --template={{.status.hostIP}}
```

You can also use router shards to ensure that the router is filtered to specific namespaces or routes, or set any environment variables after router creation. In this case create a router for each shard.

4.2.3. Other Basic Router Commands

Checking the Default Router

The default router service account, named **router**, is automatically created during quick and advanced installations. To verify that this account already exists:

```
$ oadm router --dry-run --service-account=router
```

Viewing the Default Router

To see what the default router would look like if created:

```
$ oc adm router --dry-run -o yaml --service-account=router
```

Deploying the Router to a Labeled Node

To deploy the router to any node(s) that match a specified node label:

For example, if you want to create a router named **router** and have it placed on a node labeled with **region=infra**:

```
$ oadm router router --replicas=1 --selector='region=infra' \
    --service-account=router
```

During advanced installation, the openshift_hosted_router_selector and

openshift_registry_selector Ansible settings are set to **region=infra** by default. The default router and registry will only be automatically deployed if a node exists that matches the **region=infra** label.

Multiple instances are created on different hosts according to the scheduler policy.

Using a Different Router Image

To use a different router image and view the router configuration that would be used:

For example:

```
$ oadm router region-west -o yaml --images=myrepo/somerouter:mytag \
    --service-account=router
```

4.2.4. Filtering Routes to Specific Routers

Using the **ROUTE_LABELS** environment variable, you can filter routes so that they are used only by specific routers.

For example, if you have multiple routers, and 100 routes, you can attach labels to the routes so that a portion of them are handled by one router, whereas the rest are handled by another.

1. After creating a router, use the ROUTE_LABELS environment variable to tag the router:

```
$ oc env dc/<router=name> ROUTE_LABELS="key=value"
```

2. Add the label to the desired routes:

```
oc label route <route=name> key=value
```

3. To verify that the label has been attached to the route, check the route configuration:

```
$ oc describe dc/<route_name>
```

Setting the Maximum Number of Concurrent Connections

The router can handle a maximum number of 20000 connections by default. You can change that limit depending on your needs. Having too few connections prevents the health check from working, which causes unnecessary restarts. You need to configure the system to support the maximum number of connections. The limits shown in 'sysctl fs.nr_open' and 'sysctl fs.file-max' must be large enough. Otherwise, HAproxy will not start.

When the router is created, the --max-connections= option sets the desired limit:

```
$ oadm router --max-connections=10000 ...
```

Edit the ROUTER_MAX_CONNECTIONS environment variable in the router's deployment configuration to change the value. The router pods are restarted with the new value. If ROUTER_MAX_CONNECTIONS is not present, the default value of 20000, is used.

4.2.5. Highly-Available Routers

You can set up a highly-available router on your OpenShift Container Platform cluster using IP failover. This setup has multiple replicas on different nodes so the failover software can switch to another replica if the current one fails.

4.2.6. Customizing the Router Service Ports

You can customize the service ports that a template router binds to by setting the environment variables ROUTER_SERVICE_HTTP_PORT and ROUTER_SERVICE_HTTPS_PORT. This can be done by creating a template router, then editing its deployment configuration.

The following example creates a router deployment with 0 replicas and customizes the router service HTTP and HTTPS ports, then scales it appropriately (to 1 replica).

IMPORTANT

If you do customize the template router service ports, you will also need to ensure that the nodes where the router pods run have those custom ports opened in the firewall (either via Ansible or iptables, or any other custom method that you use via firewall-cmd).

The following is an example using iptables to open the custom router service ports.

```
$ iptables -A INPUT -p tcp --dport 10080 -j ACCEPT
$ iptables -A INPUT -p tcp --dport 10443 -j ACCEPT
```

4.2.7. Working With Multiple Routers

An administrator can create multiple routers with the same definition to serve the same set of routes. Each router will be on a different node and will have a different IP address. The network administrator will need to get the desired traffic to each node.

Multiple routers can be grouped to distribute routing load in the cluster and separate tenants to different routers or shards. Each router or shard in the group admits routes based on the selectors in the router. An administrator can create shards over the whole cluster using ROUTE_LABELS. A user can create shards over a namespace (project) by using NAMESPACE_LABELS.

4.2.8. Adding a Node Selector to a Deployment Configuration

Making specific routers deploy on specific nodes requires two steps:

1. Add a label to the desired node:

```
$ oc label node 10.254.254.28 "router=first"
```

2. Add a node selector to the router deployment configuration:

```
$ oc edit dc <deploymentConfigName>
```

Add the template.spec.nodeSelector field with a key and value corresponding to the label:

```
template:
metadata:
creationTimestamp: null
labels:
router: router1
spec:
nodeSelector:
router: "first"
```

The key and value are router and first, respectively, corresponding to the router=first label.

4.2.9. Using Router Shards

Router sharding uses NAMESPACE_LABELS and/or ROUTE_LABELS, that enable a router to filter out the namespaces and/or routes that it should admit. This enables you to partition routes amongst multiple router deployments effectively distributing the set of routes.

By default, a router selects all routes from all projects (namespaces). Sharding adds labels to routes and each router shard selects routes with specific labels.

NOTE

The router service account must have the [cluster reader] permission set to allow access to labels in other namespaces.

Router Sharding and DNS

Because an external DNS server is needed to route requests to the desired shard, the administrator is responsible for making a separate DNS entry for each router in a project. A router will not forward unknown routes to another router.

For example:

- If Router A lives on host 192.168.0.5 and has routes with *.foo.com.
- And Router B lives on host 192.168.1.9 and has routes with *.example.com.

Separate DNS entries must resolve *.foo.com to the node hosting Router A and *.example.com to the node hosting Router B:

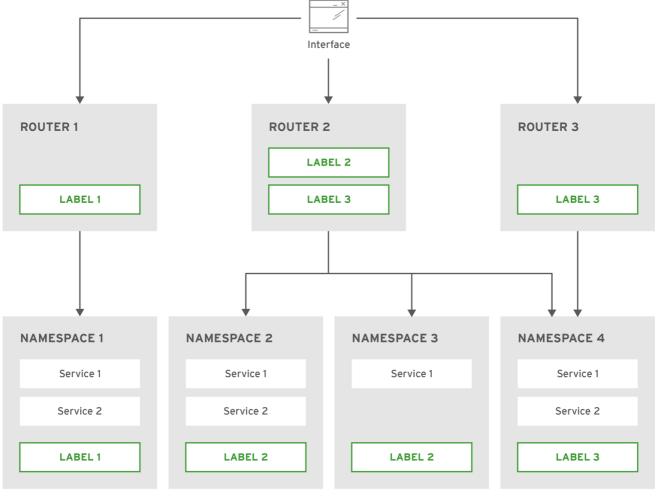

• *.foo.com A IN 192.168.0.5

• *.example.com A IN 192.168.1.9

Router Sharding Examples

This section describes router sharding using project (namespace) labels or project (namespace) names.

Figure 4.1. Router Sharding Based on Namespace Labels

OPENSHIFT 415490 0217

Example: A router deployment finops-router is run with route selector NAMESPACE_LABELS="name in (finance, ops)" and a router deployment dev-router is run with route selector NAMESPACE LABELS="name=dev".

If all routes are in the three namespaces **finance**, **ops** or **dev**, then this could effectively distribute your routes across two router deployments.

In the above scenario, sharding becomes a special case of partitioning with no overlapping sets. Routes are divided amongst multiple router shards.

The criteria for route selection governs how the routes are distributed. It is possible to have routes that overlap across multiple router deployments.

Example: In addition to the finops-router and dev-router in the example above, you also have devops-router, which is run with a route selector NAMESPACE_LABELS="name in (dev, ops)".

The routes in namespaces **dev** or **ops** now are serviced by two different router deployments. This becomes a case in which you have partitioned the routes with an overlapping set.

In addition, this enables you to create more complex routing rules, allowing the diversion of high priority traffic to the dedicated **finops-router**, but sending the lower priority ones to the **devops-router**.

NAMESPACE_LABELS allows filtering of the projects to service and selecting all the routes from those projects, but you may want to partition routes based on other criteria in the routes themselves. The ROUTE_LABELS selector allows you to slice-and-dice the routes themselves.

Example: A router deployment prod-router is run with route selector ROUTE_LABELS="mydeployment=prod" and a router deployment devtest-router is run with route selector ROUTE_LABELS="mydeployment in (dev, test)".

The example assumes you have all the routes you want to be serviced tagged with a label "mydeployment=<tag>".

Interface **ROUTER 1 ROUTER 2 ROUTER 3 NAMESPACE 1 NAMESPACE 2 NAMESPACE 2 NAMESPACE 3** NAMESPACE 4 **NAMESPACE 1 NAMESPACE 2 NAMESPACE 3 NAMESPACE 4** Service 1 Service 1 Service 1 Service 1 Service 2 Service 2 Service 2

Figure 4.2. Router Sharding Based on Namespace Names

OPENSHIFT_415490_0217

4.2.9.1. Creating Router Shards

To implement router sharding set labels on the routes in the pool and express the desired subset of those routes for the router to admit with a selection expression via the oc set env command.

First, ensure that service account associated with the router has the cluster reader permission.

The rest of this section describes an extended example. Suppose there are 26 routes, named a-z, in the pool, with various labels:

Possible labels on routes in the pool

sla=high	geo=east	hw=modest	dept=finance
sla=medium	geo=west	hw=strong	dept=dev
sla=low			dept=ops

These labels express the concepts: service level agreement, geographical location, hardware requirements, and department. The routes in the pool can have at most one label from each column. Some routes may have other labels, entirely, or none at all.

Name(s)	SLA	Geo	HW	Dept	Other Labels
a	high	east	modest	finance	type=static
b		west	strong		type=dynamic
c,d,e	low		modest		type=static
g – k	medium		strong	dev	
1-s	high		modest	ops	
t-z		west			type=dynamic

Here is a convenience script *mkshard* that ilustrates how oadm router, oc set env, and oc scale work together to make a router shard.

- The created router has name router-shard-<id>.
- Specify no scaling for now.
- The deployment configuration for the router.
- Set the selection expression using oc set env. The selection expression is the value of the ROUTE_LABELS environment variable.
- Scale it up.

Running *mkshard* several times creates several routers:

Router	Selection Expression	Routes
router-shard-1	sla=high	a,1-s
router-shard-2	geo=west	b, t – z
router-shard-3	dept=dev	g – k

4.2.9.2. Modifying Router Shards

Because a router shard is a construct based on labels, you can modify either the labels (via oc label) or the selection expression.

This section extends the example started in the Creating Router Shards section, demonstrating how to change the selection expression.

Here is a convenience script *modshard* that modifies an existing router to use a new selection expression:

```
#!/bin/bash
# Usage: modshard ID SELECTION-EXPRESSION...
id=$1
shift
router=router-shard-$id
dc=dc/$router
oc scale $dc --replicas=0
oc set env $dc "$@"
oc scale $dc --replicas=3
4
```

- The modified router has name router-shard-<id>.
- The deployment configuration where the modifications occur.
- 3 Scale it down.
- Set the new selection expression using oc set env. Unlike mkshard from the Creating Router Shards section, the selection expression specified as the non- ID arguments to modshard must include the environment variable name as well as its value.
- 5 Scale it back up.

NOTE

In modshard, the oc scale commands are not necessary if the deployment strategy for router-shard-<id> is Rolling.

For example, to expand the department for router-shard-3 to include ops as well as dev:

```
$ modshard 3 ROUTE_LABELS='dept in (dev, ops)'
```

The result is that router-shard-3 now selects routes g-s (the combined sets of g-k and 1-s).

This example takes into account that there are only three departments in this example scenario, and specifies a department to leave out of the shard, thus achieving the same result as the preceding example:

```
$ modshard 3 ROUTE_LABELS='dept != finanace'
```

This example specifies shows three comma-separated qualities, and results in only route **b** being selected:

```
$ modshard 3 ROUTE_LABELS='hw=strong,type=dynamic,geo=west'
```

Similarly to ROUTE_LABELS, which involve a route's labels, you can select routes based on the labels of the route's namespace labels, with the NAMESPACE_LABELS environment variable. This example modifies router-shard-3 to serve routes whose namespace has the label frequency=weekly:

```
$ modshard 3 NAMESPACE_LABELS='frequency=weekly'
```

The last example combines **ROUTE_LABELS** and **NAMESPACE_LABELS** to select routes with label sla=low and whose namespace has the label frequency=weekly:

```
$ modshard 3 \
    NAMESPACE_LABELS='frequency=weekly' \
    ROUTE_LABELS='sla=low'
```

4.2.9.3. Using Namespace Router Shards

The routes for a project can be handled by a selected router by using NAMESPACE_LABELS. The router is given a selector for a NAMESPACE_LABELS label and the project that wants to use the router applies the NAMESPACE_LABELS label to its namespace.

First, ensure that service account associated with the router has the **cluster reader** permission. This permits the router to read the labels that are applied to the namespaces.

Now create and label the router:

```
$ oadm router ... --service-account=router
$ oc set env dc/router NAMESPACE_LABELS="router=r1"
```

Because the router has a selector for a namespace, the router will handle routes for that namespace. So, for example:

```
$ oc label namespace default "router=r1"
```

Now create routes in the default namespace, and the route is available in the default router:

```
$ oc create -f route1.yaml
```

Now create a new project (namespace) and create a route, route2.

```
$ oc new-project p1
$ oc create -f route2.yaml
```

And notice the route is not available in your router. Now label namespace p1 with "router=r1"

```
$ oc label namespace p1 "router=r1"
```

Which makes the route available to the router.

Note that removing the label from the namespace won't have immediate effect (as we don't see the updates in the router), so if you redeploy/start a new router pod, you should see the unlabelled effects.

```
$ oc scale dc/router --replicas=0 && oc scale dc/router --replicas=1
```

4.2.10. Finding the Host Name of the Router

When exposing a service, a user can use the same route from the DNS name that external users use to access the application. The network administrator of the external network must make sure the host name resolves to the name of a router that has admitted the route. The user can set up their DNS with a CNAME that points to this host name. However, the user may not know the host name of the router. When it is not known, the cluster administrator can provide it.

The cluster administrator can use the **--router-canonical-hostname** option with the router's canonical host name when creating the router. For example:

```
# oadm router myrouter --router-canonical-hostname="rtr.example.com"
```

This creates the **ROUTER_CANONCAL_HOSTNAME** environment variable in the router's deployment configuration containing the host name of the router.

For routers that already exist, the cluster administrator can edit the router's deployment configuration and add the ROUTER_CANONICAL_HOSTNAME environment variable:

```
spec:
template:
spec:
containers:
env:
name: ROUTER_CANONCAL_HOSTNAME
value: rtr.example.com
```

The **ROUTER_CANONICAL_HOSTNAME** value is displayed in the route status for all routers that have admitted the route. The route status is refreshed every time the router is reloaded.

When a user creates a route, all of the active routers evaluate the route and, if conditions are met, admit it. When a router that defines the ROUTER_CANONCAL_HOSTNAME environment variable admits the route, the router places the value in the routerCanonicalHostname field in the route status. The user can examine the route status to determine which, if any, routers have admitted the route, select a router from the list, and find the host name of the router to pass along to the network administrator.

```
status:
ingress:
```

```
conditions:
```

lastTransitionTime: 2016-12-07T15:20:57Z

status: "True"
type: Admitted

host: hello.in.mycloud.com

routerCanonicalHostname: rtr.example.com

routerName: myrouter
wildcardPolicy: None

oc describe inclues the host name when available:

```
$ oc describe route/hello-route3
...
Requested Host: hello.in.mycloud.com exposed on router myroute (host rtr.example.com) 12 minutes ago
```

Using the above information, the user can ask the DNS administrator to set up a CNAME from the route's host, hello.in.mycloud.com, to the router's canonical hostname, rtr.example.com. This results in any traffic to hello.in.mycloud.com reaching the user's application.

4.2.11. Customizing the Default Routing Subdomain

You can customize the suffix used as the default routing subdomain for your environment by modifying the master configuration file (the /etc/origin/master/master-config.yaml file by default). Routes that do not specify a host name would have one generated using this default routing subdomain.

The following example shows how you can set the configured suffix to v3.openshift.test:

```
routingConfig:
   subdomain: v3.openshift.test
```

NOTE

This change requires a restart of the master if it is running.

With the OpenShift Container Platform master(s) running the above configuration, the generated host name for the example of a route named **no-route-hostname** without a host name added to a namespace **mynamespace** would be:

no-route-hostname-mynamespace.v3.openshift.test

4.2.12. Forcing Route Host Names to a Custom Routing Subdomain

If an administrator wants to restrict all routes to a specific routing subdomain, they can pass the -force-subdomain option to the oadm router command. This forces the router to override any host
names specified in a route and generate one based on the template provided to the --forcesubdomain option.

The following example runs a router, which overrides the route host names using a custom subdomain template n=0, apps.example.com.

\$ oadm router --force-subdomain='\${name}-\${namespace}.apps.example.com'

4.2.13. Using Wildcard Certificates

A TLS-enabled route that does not include a certificate uses the router's default certificate instead. In most cases, this certificate should be provided by a trusted certificate authority, but for convenience you can use the OpenShift Container Platform CA to create the certificate. For example:

NOTE

The oadm ca create-server-cert command generates a certificate that is valid for two years. This can be altered with the --expire-days option, but for security reasons, it is recommended to not make it greater than this value.

The router expects the certificate and key to be in PEM format in a single file:

\$ cat cloudapps.crt cloudapps.key \$CA/ca.crt > cloudapps.router.pem

From there you can use the --default-cert flag:

\$ oadm router --default-cert=cloudapps.router.pem --service-account=router

NOTE

Browsers only consider wildcards valid for subdomains one level deep. So in this example, the certificate would be valid for *a.cloudapps.example.com* but not for *a.b.cloudapps.example.com*.

4.2.14. Manually Redeploy Certificates

To manually redeploy the router certificates:

1. Check to see if a secret containing the default router certificate was added to the router:

```
$ oc volumes dc/router

deploymentconfigs/router
  secret/router-certs as server-certificate
  mounted at /etc/pki/tls/private
```

If the certificate is added, skip the following step and overwrite the secret.

2. Make sure that you have a default certificate directory set for the following variable **DEFAULT_CERTIFICATE_DIR**:

```
$ oc env dc/router --list
DEFAULT_CERTIFICATE_DIR=/etc/pki/tls/private
```

If not, create the directory using the following command:

```
$ oc env dc/router DEFAULT_CERTIFICATE_DIR=/etc/pki/tls/private
```

3. Export the certificate to PEM format:

```
$ cat custom-router.crt custom-ca.crt > custom-router.pem
```

4. Overwrite or create a router certificate secret:

If the certificate secret was added to the router, overwrite the secret. If not, create a new secret.

To overwrite the secret, run the following command:

```
$ oc secrets new router-certs tls.crt=custom-router.crt
tls.key=custom-router.key -o json --type='kubernetes.io/tls' --
confirm | oc replace -f -
```

To create a new secret, run the following commands:

```
$ oc secrets new router-certs tls.crt=custom-router.crt
tls.key=custom-router.key --type='kubernetes.io/tls' --confirm
$ oc volume dc/router --add --mount-path=/etc/pki/tls/private --
secret-name='router-certs' --name router-certs
```

5. Deploy the router.

```
$ oc rollout latest router
```

4.2.15. Using Secured Routes

Currently, password protected key files are not supported. HAProxy prompts for a password upon starting and does not have a way to automate this process. To remove a passphrase from a keyfile, you can run:

```
# openssl rsa -in <passwordProtectedKey.key> -out <new.key>
```

Here is an example of how to use a secure edge terminated route with TLS termination occurring on the router before traffic is proxied to the destination. The secure edge terminated route specifies the TLS certificate and key information. The TLS certificate is served by the router front end.

First, start up a router instance:

```
# oadm router --replicas=1 --service-account=router
```

Next, create a private key, csr and certificate for our edge secured route. The instructions on how to do that would be specific to your certificate authority and provider. For a simple self-signed certificate for a domain named www.example.test, see the example shown below:

```
# sudo openssl genrsa -out example-test.key 2048
#
# sudo openssl req -new -key example-test.key -out example-test.csr \
    -subj "/C=US/ST=CA/L=Mountain View/0=0S3/0U=Eng/CN=www.example.test"
#
# sudo openssl x509 -req -days 366 -in example-test.csr \
    -signkey example-test.key -out example-test.crt
```

Generate a route using the above certificate and key.

```
$ oc create route edge --service=my-service \
    --hostname=www.example.test \
    --key=example-test.key --cert=example-test.crt
route "my-service" created
```

Look at its definition.

```
$ oc get route/my-service -o yaml
apiVersion: v1
kind: Route
metadata:
  name: my-service
spec:
 host: www.example.test
  to:
    kind: Service
    name: my-service
  tls:
    termination: edge
    key: |
     ----BEGIN PRIVATE KEY----
      [...]
      ----END PRIVATE KEY----
    certificate: |
      ----BEGIN CERTIFICATE----
      [...]
      ----END CERTIFICATE----
```

Make sure your DNS entry for www.example.test points to your router instance(s) and the route to your domain should be available. The example below uses curl along with a local resolver to simulate the DNS lookup:

```
# routerip="4.1.1.1" # replace with IP address of one of your router instances.
# curl -k --resolve www.example.test:443:$routerip https://www.example.test/
```

4.2.16. Using Wildcard Routes (for a Subdomain)

The HAProxy router has support for wildcard routes, which are enabled by setting the

ROUTER_ALLOW_WILDCARD_ROUTES environment variable to true. Any routes with a wildcard policy of **Subdomain** that pass the router admission checks will be serviced by the HAProxy router. Then, the HAProxy router exposes the associated service (for the route) per the route's wildcard policy.

```
$ oadm router --replicas=0 ...
$ oc set env dc/router ROUTER_ALLOW_WILDCARD_ROUTES=true
$ oc scale dc/router --replicas=1
```

Learn how to configure the web console for wildcard routes.

Using a Secure Wildcard Edge Terminated Route

This example reflects TLS termination occurring on the router before traffic is proxied to the destination. Traffic sent to any hosts in the subdomain example.org (*.example.org) is proxied to the exposed service.

The secure edge terminated route specifies the TLS certificate and key information. The TLS certificate is served by the router front end for all hosts that match the subdomain (*.example.org).

1. Start up a router instance:

```
$ oadm router --replicas=0 --service-account=router
$ oc set env dc/router ROUTER_ALLOW_WILDCARD_ROUTES=true
$ oc scale dc/router --replicas=1
```

2. Create a private key, certificate signing request (CSR), and certificate for the edge secured route.

The instructions on how to do this are specific to your certificate authority and provider. For a simple self-signed certificate for a domain named *.example.test, see this example:

```
# sudo openssl genrsa -out example-test.key 2048
#
# sudo openssl req -new -key example-test.key -out example-test.csr
-subj "/C=US/ST=CA/L=Mountain View/0=OS3/OU=Eng/CN=*.example.test"
# sudo openssl x509 -req -days 366 -in example-test.csr \
-signkey example-test.key -out example-test.crt
```

3. Generate a wildcard route using the above certificate and key:

```
$ cat > route.yaml <<REOF
apiVersion: v1
kind: Route
metadata:
   name: my-service
spec:
   host: www.example.test
   wildcardPolicy: Subdomain
   to:
     kind: Service
     name: my-service
tls:
     termination: edge
   key: "$(perl -pe 's/\n/\\n/' example-test.key)"</pre>
```

```
certificate: "$(perl -pe 's/\n/\\n/' example-test.cert)"
REOF
$ oc create -f route.yaml
```

Ensure your DNS entry for *.example.test points to your router instance(s) and the route to your domain is available.

This example uses curl with a local resolver to simulate the DNS lookup:

```
# routerip="4.1.1.1" # replace with IP address of one of your
router instances.
# curl -k --resolve www.example.test:443:$routerip
https://www.example.test/
# curl -k --resolve abc.example.test:443:$routerip
https://abc.example.test/
# curl -k --resolve anyname.example.test:443:$routerip
https://anyname.example.test/
```

For routers that allow wildcard routes (ROUTER_ALLOW_WILDCARD_ROUTES set to true), there are some caveats to the ownership of a subdomain associated with a wildcard route.

Prior to wildcard routes, ownership was based on the claims made for a host name with the namespace with the oldest route winning against any other claimants. For example, route r1 in namespace ns1 with a claim for one.example.test would win over another route r2 in namespace ns2 for the same host name one.example.test if route r1 was older than route r2.

In addition, routes in other namespaces were allowed to claim non-overlapping hostnames. For example, route rone in namespace ns1 could claim www.example.test and another route rtwo in namespace d2 could claim c3po.example.test.

This is still the case if there are *no* wildcard routes claiming that same subdomain (example.test in the above example).

However, a wildcard route needs to claim all of the host names within a subdomain (host names of the form *.example.test). A wildcard route's claim is allowed or denied based on whether or not the oldest route for that subdomain (example.test) is in the same namespace as the wildcard route. The oldest route can be either a regular route or a wildcard route.

For example, if there is already a route eldest that exists in the ns1 namespace that claimed a host named owner.example.test and, if at a later point in time, a new wildcard route wildthing requesting for routes in that subdomain (example.test) is added, the claim by the wildcard route will only be allowed if it is the same namespace (ns1) as the owning route.

The following examples illustrate various scenarios in which claims for wildcard routes will succeed or fail.

In the example below, a router that allows wildcard routes will allow non-overlapping claims for hosts in the subdomain example.test as long as a wildcard route has not claimed a subdomain.

```
$ oadm router ...
$ oc set env dc/router
$ oc project ns1 ROUTER_ALLOW_WILDCARD_ROUTES=true

$ oc project ns1
$ oc expose service myservice --hostname=owner.example.test
```

```
$ oc expose service myservice --hostname=aname.example.test
$ oc expose service myservice --hostname=bname.example.test

$ oc project ns2
$ oc expose service anotherservice --hostname=second.example.test
$ oc expose service anotherservice --hostname=cname.example.test

$ oc project otherns
$ oc expose service thirdservice --hostname=emmy.example.test
$ oc expose service thirdservice --hostname=webby.example.test
```

In the example below, a router that allows wildcard routes will not allow the claim for owner.example.test or aname.example.test to succeed since the owning namespace is ns1.

```
$ oadm router ...
$ oc set env dc/router ROUTER_ALLOW_WILDCARD_ROUTES=true
$ oc project ns1
$ oc expose service myservice --hostname=owner.example.test
$ oc expose service myservice --hostname=aname.example.test
$ oc project ns2
$ oc expose service secondservice --hostname=bname.example.test
$ oc expose service secondservice --hostname=cname.example.test
$ # Router will not allow this claim with a different path name `/p1` as
$ # namespace `ns1` has an older route claiming host `aname.example.test`.
$ oc expose service secondservice --hostname=aname.example.test --
path="/p1"
$ # Router will not allow this claim as namespace `ns1` has an older route
$ # claiming host name `owner.example.test`.
$ oc expose service secondservice --hostname=owner.example.test
$ oc project otherns
$ # Router will not allow this claim as namespace `ns1` has an older route
$ # claiming host name `aname.example.test`.
$ oc expose service thirdservice --hostname=aname.example.test
```

In the example below, a router that allows wildcard routes will allow the claim for `*.example.test to succeed since the owning namespace is ns1 and the wildcard route belongs to that same namespace.

```
$ oadm router ...
$ oc set env dc/router ROUTER_ALLOW_WILDCARD_ROUTES=true

$ oc project ns1
$ oc expose service myservice --hostname=owner.example.test

$ # Reusing the route.yaml from the previous example.
$ # spec:
$ # host: www.example.test
```

```
$ # wildcardPolicy: Subdomain
$ oc create -f route.yaml # router will allow this claim.
```

In the example below, a router that allows wildcard routes will not allow the claim for `*.example.test to succeed since the owning namespace is ns1 and the wildcard route belongs to another namespace cyclone.

```
$ oadm router ...
$ oc set env dc/router
$ oc project ns1 ROUTER_ALLOW_WILDCARD_ROUTES=true

$ oc project ns1
$ oc expose service myservice --hostname=owner.example.test

$ # Switch to a different namespace/project.
$ oc project cyclone

$ # Reusing the route.yaml from a prior example.
$ # spec:
$ # host: www.example.test
$ # wildcardPolicy: Subdomain

$ oc create -f route.yaml # router will deny (_NOT_ allow) this claim.
```

Similarly, once a namespace with a wildcard route claims a subdomain, only routes within that namespace can claim any hosts in that same subdomain.

In the example below, once a route in namespace ns1 with a wildcard route claims subdomain example.test, only routes in the namespace ns1 are allowed to claim any hosts in that same subdomain.

```
$ oadm router ...
$ oc set env dc/router
$ oc project ns1 ROUTER_ALLOW_WILDCARD_ROUTES=true
$ oc project ns1
$ oc expose service myservice --hostname=owner.example.test
$ oc project otherns
$ # namespace `otherns` is allowed to claim for other.example.test
$ oc expose service otherservice --hostname=other.example.test
$ oc project ns1
$ # Reusing the route.yaml from the previous example.
$ # spec:
     host: www.example.test
     wildcardPolicy: Subdomain
$ oc create -f route.yaml
                          # Router will allow this claim.
    In addition, route in namespace otherns will lose its claim to host
     `other.example.test` due to the wildcard route claiming the
```

subdomain.

\$ # namespace `ns1` is allowed to claim for deux.example.test
\$ oc expose service mysecondservice --hostname=deux.example.test

\$ # namespace `ns1` is allowed to claim for deux.example.test with path
/p1
\$ oc expose service mythirdservice --hostname=deux.example.test -path="/p1"

\$ oc project otherns

\$ # namespace `otherns` is not allowed to claim for deux.example.test
\$ # with a different path '/otherpath'
\$ oc expose service otherservice --hostname=deux.example.test -path="/otherpath"

\$ # namespace `otherns` is not allowed to claim for owner.example.test
\$ oc expose service yetanotherservice --hostname=owner.example.test
\$ # namespace `otherns` is not allowed to claim for unclaimed.example.test
\$ oc expose service yetanotherservice --hostname=unclaimed.example.test

In the example below, different scenarios are shown, in which the owner routes are deleted and ownership is passed within and across namespaces. While a route claiming host eldest.example.test in the namespace ns1 exists, wildcard routes in that namespace can claim subdomain example.test. When the route for host eldest.example.test is deleted, the next oldest route senior.example.test would become the oldest route and would not affect any other routes. Once the route for host senior.example.test is deleted, the next oldest route junior.example.test becomes the oldest route and block the wildcard route claimant.

```
$ oadm router ...
$ oc set env dc/router
$ oc project ns1 ROUTER_ALLOW_WILDCARD_ROUTES=true
$ oc project ns1
$ oc expose service myservice --hostname=eldest.example.test
$ oc expose service seniorservice --hostname=senior.example.test
$ oc project otherns
$ # namespace `otherns` is allowed to claim for other.example.test
$ oc expose service juniorservice --hostname=junior.example.test
$ oc project ns1
$ # Reusing the route.yaml from the previous example.
$ #
    host: www.example.test
$ # wildcardPolicy: Subdomain
$ oc create -f route.yaml # Router will allow this claim.
    In addition, route in namespace otherns will lose its claim to host
    `junior.example.test` due to the wildcard route claiming the
subdomain.
```

```
$ # namespace `ns1` is allowed to claim for dos.example.test
$ oc expose service mysecondservice --hostname=dos.example.test
$ # Delete route for host `eldest.example.test`, the next oldest route is
$ # the one claiming `senior.example.test`, so route claims are
unaffacted.
$ oc delete route myservice

$ # Delete route for host `senior.example.test`, the next oldest route is
$ # the one claiming `junior.example.test` in another namespace, so claims
$ # for a wildcard route would be affected. The route for the host
$ # `dos.example.test` would be unaffected as there are no other wildcard
$ # claimants blocking it.
$ oc delete route seniorservice
```

4.2.17. Using the Container Network Stack

The OpenShift Container Platform router runs inside a container and the default behavior is to use the network stack of the host (i.e., the node where the router container runs). This default behavior benefits performance because network traffic from remote clients does not need to take multiple hops through user space to reach the target service and container.

Additionally, this default behavior enables the router to get the actual source IP address of the remote connection rather than getting the node's IP address. This is useful for defining ingress rules based on the originating IP, supporting sticky sessions, and monitoring traffic, among other uses.

This host network behavior is controlled by the --host-network router command line option, and the default behaviour is the equivalent of using --host-network=true. If you wish to run the router with the container network stack, use the --host-network=false option when creating the router. For example:

```
$ oadm router --service-account=router --host-network=false
```

Internally, this means the router container must publish the 80 and 443 ports in order for the external network to communicate with the router.

NOTE

Running with the container network stack means that the router sees the source IP address of a connection to be the NATed IP address of the node, rather than the actual remote IP address.

NOTE

On OpenShift Container Platform clusters using multi-tenant network isolation, routers on a non-default namespace with the --host-network=false option will load all routes in the cluster, but routes across the namespaces will not be reachable due to network isolation. With the --host-network=true option, routes bypass the container network and it can access any pod in the cluster. If isolation is needed in this case, then do not add routes across the namespaces.

4.2.18. Exposing Router Metrics

Using the --metrics-image and --expose-metrics options, you can configure the OpenShift Container Platform router to run a sidecar container that exposes or publishes router metrics for consumption by external metrics collection and aggregation systems (e.g. Prometheus, statsd).

Depending on your router implementation, the image is appropriately set up and the metrics sidecar container is started when the router is deployed. For example, the HAProxy-based router implementation defaults to using the prom/haproxy-exporter image to run as a sidecar container, which can then be used as a metrics datasource by the Prometheus server.

NOTE

The --metrics-image option overrides the defaults for HAProxy-based router implementations and, in the case of custom implementations, enables the image to use for a custom metrics exporter or publisher.

1. Grab the HAProxy Prometheus exporter image from the Docker registry:

```
$ sudo docker pull prom/haproxy-exporter
```

2. Create the OpenShift Container Platform router:

```
$ oadm router --service-account=router --expose-metrics
```

Or, optionally, use the --metrics-image option to override the HAProxy defaults:

```
$ oadm router --service-account=router --expose-metrics \
    --metrics-image=prom/haproxy-exporter
```

3. Once the haproxy-exporter containers (and your HAProxy router) have started, point Prometheus to the sidecar container on port 9101 on the node where the haproxy-exporter container is running:

```
$ haproxy_exporter_ip="<enter-ip-address-or-hostname>"
$ cat > haproxy-scraper.yml <<CFGEOF</pre>
global:
  scrape_interval: "60s"
  scrape_timeout:
                   "10s"
  # external_labels:
    # source: openshift-router
scrape_configs:
  - job_name: "haproxy"
    target_groups:
      - targets:
        - "${haproxy_exporter_ip}:9101"
CFGEOF
$ # And start prometheus as you would normally using the above
config file.
$ echo "
          - Example: prometheus -config.file=haproxy-scraper.yml "
$ echo "
                      or you can start it as a container on
{product-title}!!
```

```
$ echo " - Once the prometheus server is up, view the {product-
title} HAProxy "
$ echo " router metrics at:
http://<ip>:9090/consoles/haproxy.html "
```

4.2.19. Preventing Connection Failures During Restarts

If you connect to the router while the proxy is reloading, there is a small chance that your connection will end up in the wrong network queue and be dropped. The issue is being addressed. In the meantime, it is possible to work around the problem by installing <code>iptables</code> rules to prevent connections during the reload window. However, doing so means that the router needs to run with elevated privilege so that it can manipulate <code>iptables</code> on the host. It also means that connections that happen during the reload are temporarily ignored and must retransmit their connection start, lengthening the time it takes to connect, but preventing connection failure.

To prevent this, configure the router to use **iptables** by changing the service account, and setting an environment variable on the router.

Use a Privileged SCC

When creating the router, allow it to use the privileged SCC. This gives the router user the ability to create containers with root privileges on the nodes:

```
$ oc adm policy add-scc-to-user privileged -z router
```

Patch the Router Deployment Configuration to Create a Privileged Container

You can now create privileged containers. Next, configure the router deployment configuration to use the privilege so that the router can set the iptables rules it needs. This patch changes the router deployment configuration so that the container that is created runs as privileged (and therefore gets correct capabilities) and run as root:

```
$ oc patch dc router -p '{"spec":{"template":{"spec":{"containers":
   [{"name":"router","securityContext":
   {"privileged":true}}],"securityContext":{"runAsUser": 0}}}}'
```

Configure the Router to Use iptables

Set the option on the router deployment configuration:

```
$ oc set env dc/router -c router DROP_SYN_DURING_RESTART=true
```

If you used a non-default name for the router, you must change *dc/router* accordingly.

4.2.20. ARP Cache Tuning for Large-scale Clusters

In OpenShift Container Platform clusters with large numbers of routes (greater than the value of net.ipv4.neigh.default.gc_thresh3, which is 1024 by default), you must increase the default values of sysctl variables to allow more entries in the ARP cache.

The kernel messages would be similar to the following:

```
[ 1738.811139] net_ratelimit: 1045 callbacks suppressed
[ 1743.823136] net_ratelimit: 293 callbacks suppressed
```

When this issue occurs, the oc commands might start to fail with the following error:

```
Unable to connect to the server: dial tcp: lookup <hostname> on <ip>: <port>: write udp <ip>:<port>-><ip>:<port>: write: invalid argument
```

To verify the actual amount of ARP entries for IPv4, run the following:

```
# ip -4 neigh show nud all | wc -1
```

If the number begins to approach the net.ipv4.neigh.default.gc_thresh3 threshold, increase the values. Run the following on the nodes running the router pods. The following sysctl values are suggested for clusters with large numbers of routes:

```
net.ipv4.neigh.default.gc_thresh1 = 8192
net.ipv4.neigh.default.gc_thresh2 = 32768
net.ipv4.neigh.default.gc_thresh3 = 65536
```

To make these settings permanent across reboots, create a custom tuned profile.

4.2.21. Protecting Against DDoS Attacks

Add **timeout http-request** to the default HAProxy router image to protect the deployment against distributed denial-of-service (DDoS) attacks (for example, slowloris):

timeout http-request is set up to 5 seconds. HAProxy gives a client 5 seconds *to send its whole HTTP request. Otherwise, HAProxy shuts the connection with *an error.

Also, when the environment variable **ROUTER_SLOWLORIS_TIMEOUT** is set, it limits the amount of time a client has to send the whole HTTP request. Otherwise, HAProxy will shut down the connection.

Setting the environment variable allows information to be captured as part of the router's deployment configuration and does not require manual modification of the template, whereas manually adding the HAProxy setting requires you to rebuild the router pod and maintain your router template file.

Using annotations implements basic DDoS protections in the HAProxy template router, including the ability to limit the:

- number of concurrent TCP connections
- rate at which a client can request TCP connections

rate at which HTTP requests can be made

These are enabled on a per route basis because applications can have extremely different traffic patterns.

Table 4.1. HAProxy Template Router Settings

Setting	Description
haproxy.router.openshift.io/rate- limit-connections	Enables the settings be configured (when set to true , for example).
haproxy.router.openshift.io/rate- limit-connections.concurrent-tcp	The number of concurrent TCP connections that can be made by the same IP address on this route.
haproxy.router.openshift.io/rate- limit-connections.rate-tcp	The number of TCP connections that can be opened by a client IP.
haproxy.router.openshift.io/rate- limit-connections.rate-http	The number of HTTP requests that a client IP can make in a 3-second period.

4.3. DEPLOYING A CUSTOMIZED HAPROXY ROUTER

4.3.1. Overview

The default HAProxy router is intended to satisfy the needs of most users. However, it does not expose all of the capability of HAProxy. Therefore, users may need to modify the router for their own needs.

You may need to implement new features within the application back-ends, or modify the current operation. The router plug-in provides all the facilities necessary to make this customization.

The router pod uses a template file to create the needed HAProxy configuration file. The template file is a golang template. When processing the template, the router has access to OpenShift Container Platform information, including the router's deployment configuration, the set of admitted routes, and some helper functions.

When the router pod starts, and every time it reloads, it creates an HAProxy configuration file, and then it starts HAProxy. The HAProxy configuration manual describes all of the features of HAProxy and how to construct a valid configuration file.

A configMap can be used to add the new template to the router pod. With this approach, the router deployment configuration is modified to mount the configMap as a volume in the router pod. The TEMPLATE_FILE environment variable is set to the full path name of the template file in the router pod.

Alternatively, you can build a custom router image and use it when deploying some or all of your routers. There is no need for all routers to run the same image. To do this, modify the *haproxy-template.config* file, and rebuild the router image. The new image is pushed to the the cluster's Docker repository, and the router's deployment configuration *image*: field is updated with the new name. When the cluster is updated, the image needs to be rebuilt and pushed.

In either case, the router pod starts with the template file.

4.3.2. Obtaining the Router Configuration Template

The HAProxy template file is fairly large and complex. For some changes, it may be easier to modify the existing template rather than writing a complete replacement. You can obtain a *haproxy-config.template* file from a running router by running this on master, referencing the router pod:

Alternatively, you can log onto the node that is running the router:

```
# docker run --rm --interactive=true --tty --entrypoint=cat \
    registry.access.redhat.com/openshift3/ose-haproxy-router:$version
haproxy-config.template
```

The image name is from docker images.

Save this content to a file for use as the basis of your customized template. The saved *haproxy.config* shows what is actually running.

4.3.3. Modifying the Router Configuration Template

4.3.3.1. Background

The template is based on the golang template. It can reference any of the environment variables in the router's deployment configuration, any configuration information that is described below, and router provided helper functions.

The structure of the template file mirrors the resulting HAProxy configuration file. As the template is processed, anything not surrounded by {{" something "}} is directly copied to the configuration file. Passages that are surrounded by {{" something "}} are evaluated. The resulting text, if any, is copied to the configuration file.

4.3.3.2. Go Template Actions

The **define** action names the file that will contain the processed template.

```
{{define "/var/lib/haproxy/conf/haproxy.config"}}pipeline{{end}}
```

Table 4.2. Template Router Functions

Function	Meaning
endpointsForAlias(alias ServiceAliasConfig, svc ServiceUnit) []Endpoint	Returns the list of valid endpoints.

Function	Meaning
env(variable, default string) string	Tries to get the named environment variable from the pod. Returns the second argument if the variable cannot be read or is empty.
matchPattern(pattern, s string) bool	The first argument is a string that contains the regular expression, the second argument is the variable to test. Returns a Boolean value indicating whether the regular expression provided as the first argument matches the string provided as the second argument.
isInteger(s string) bool	Determines if a given variable is an integer.
matchValues(s string, allowedValues string) bool	Compares a given string to a list of allowed strings.
<pre>genSubdomainWildcardRegexp(hostname, path string, exactPath bool) string</pre>	Generates a regular expression matching the subdomain for hosts (and paths) with a wildcard policy.
generateRouteRegexp(hostname, path string, wildcard bool) string	Generates a regular expression matching the route hosts (and paths). The first argument is the host name, the second is the path, and the third is a wildcard Boolean.
genCertificateHostName(hostname string, wildcard bool) string	Generates host name to use for serving/matching certificates. First argument is the host name and the second is the wildcard Boolean.

These functions are provided by the HAProxy template router plug-in.

4.3.3.3. Router Provided Information

This section reviews the OpenShift Container Platform information that the router makes available to the template. The router configuration parameters are the set of data that the HAProxy router plug-in is given. The fields are accessed by (dot) .Fieldname.

The tables below the Router Configuration Parameters expand on the definitions of the various fields. In particular, .State has the set of admitted routes.

Table 4.3. Router Configuration Parameters

Field	Туре	Description
WorkingDir	string	The directory that files will be written to, defaults to /var/lib/containers/router

Field	Туре	Description
State	<pre>map[string] (ServiceAliasConfig)`</pre>	The routes.
ServiceUnits	map[string]ServiceUnit	The service lookup.
DefaultCertificate	string	Full path name to the default certificate in pem format.
PeerEndpoints	`[]Endpoint	Peers.
StatsUser	string	User name to expose stats with (if the template supports it).
StatsPassword	string	Password to expose stats with (if the template supports it).
StatsPort	int	Port to expose stats with (if the template supports it).
BindPorts	bool	Whether the router should bind the default ports.

Table 4.4. Router ServiceAliasConfig (A Route)

Field	Туре	Description
Name	string	The user-specified name of the route.
Namespace	string	The namespace of the route.
Host	string	The host name. For example, www.example.com.
Path	string	Optional path. For example, www.example.com/myservice where myservice is the path.
TLSTermination	routeapi.TLSTermination Type	The termination policy for this back-end; drives the mapping files and router configuration.
Certificates	map[string]Certificate	Certificates used for securing this back-end. Keyed by the certificate ID.

Field	Туре	Description
Status	ServiceAliasConfigStatu s	Indicates the status of configuration that needs to be persisted.
PreferPort	string	Indicates the port the user wants to expose. If empty, a port will be selected for the service.
InsecureEdgeTermination Policy	routeapi.InsecureEdgeTe rminationPolicyType	Indicates desired behavior for insecure connections to an edgeterminated route: none (or disable), allow, or redirect.
RoutingKeyName	string	Hash of the route + namespace name used to obscure the cookie ID.
IsWildcard	bool	Indicates this service unit needing wildcard support.
Annotations	map[string]string	Annotations attached to this route.
ServiceUnitNames	map[string]int32	Collection of services that support this route, keyed by service name and valued on the weight attached to it with respect to other entries in the map.
ActiveServiceUnits	int	Count of the ServiceUnitNames with a non-zero weight.

Table 4.5. Router ServiceUnit

Field	Туре	Description
Name	string	Name corresponds to a service name + namespace. Uniquely identifies the ServiceUnit .

Field	Туре	Description
EndpointTable	[]Endpoint	Endpoints that back the service. This translates into a final back- end implementation for routers.

ServiceUnit is an encapsulation of a service, the endpoints that back that service, and the routes that point to the service. This is the data that drives the creation of the router configuration files

Table 4.6. Router Endpoint

Field	Туре
ID	string
IP	string
Port	string
TargetName	string
PortName	string
IdHash	string
NoHealthCheck	bool

Endpoint is an internal representation of a Kubernetes endpoint.

Table 4.7. Router Certificate, ServiceAliasConfigStatus

Field	Туре	Description
Certificate	string	Represents a public/private key pair. It is identified by an ID, which will become the file name. A CA certificate will not have a PrivateKey set.
ServiceAliasConfigStatu s	string	Indicates that the necessary files for this configuration have been persisted to disk. Valid values: "saved", "".

Table 4.8. Router Certificate Type

Field	Туре	Description
ID	string	
Contents	string	The certificate.
PrivateKey	string	The private key.

Table 4.9. Router TLSTerminationType

Field	Туре	Description
TLSTerminationType	string	Dictates where the secure communication will stop.
InsecureEdgeTermination PolicyType	string	Indicates the desired behavior for insecure connections to a route. While each router may make its own decisions on which ports to expose, this is normally port 80.

 $\textbf{TLSTerminationType} \ and \ \textbf{InsecureEdgeTerminationPolicyType} \ dictate \ where \ the \ secure \ communication \ will \ stop.$

Table 4.10. Router TLSTerminationType Values

Constant	Value	Meaning
TLSTerminationEdge	edge	Terminate encryption at the edge router.
TLSTerminationPassthrou gh	passthrough	Terminate encryption at the destination, the destination is responsible for decrypting traffic.
TLSTerminationReencrypt	reencrypt	Terminate encryption at the edge router and re-encrypt it with a new certificate supplied by the destination.

Table 4.11. Router InsecureEdgeTerminationPolicyType Values

Туре	Meaning
Allow	Traffic is sent to the server on the insecure port (default).
Disable	No traffic is allowed on the insecure port.

Туре	Meaning
Redirect	Clients are redirected to the secure port.

None ("") is the same as Disable.

4.3.3.4. Annotations

Each route can have annotations attached. Each annotation is just a name and a value.

```
apiVersion: v1
kind: Route
metadata:
   annotations:
   haproxy.router.openshift.io/timeout: 5500ms
[...]
```

The name can be anything that does not conflict with existing Annotations. The value is any string. The string can have multiple tokens separated by a space. For example, aa **bb cc**. The template uses {{index}} to extract the value of an annotation. For example:

```
{{$balanceAlgo := index $cfg.Annotations "haproxy.router.openshift.io/balance"}}
```

This is an example of how this could be used for mutual client authorization.

```
{{ with $cnList := index $cfg.Annotations "whiteListCertCommonName" }}
    {{    if ne $cnList "" }}
    acl test ssl_c_s_dn(CN) -m str {{ $cnList }}
    http-request deny if !test
    {{    end }}
    {{ end }}
```

Then, you can handle the white-listed CNs with this command.

```
$ oc annotate route <route-name> --overwrite whiteListCertCommonName="CN1
CN2 CN3"
```

See Route-specific Annotations for more information.

4.3.3.5. Environment Variables

The template can use any environment variables that exist in the router pod. The environment variables can be set in the deployment configuration. New environment variables can be added.

They are referenced by the env function:

```
{{env "ROUTER_MAX_CONNECTIONS" "20000"}}
```

The first string is the variable, and the second string is the default when the variable is missing or nil. When ROUTER_MAX_CONNECTIONS is not set or is nil, 20000 is used. Environment variables are a map where the key is the environment variable name and the content is the value of the variable.

See Route-specific Environment variables for more information.

4.3.3.6. Example Usage

Here is a simple template based on the HAProxy template file.

Start with a comment:

```
{{/*
  Here is a small example of how to work with templates
  taken from the HAProxy template file.
*/}}
```

The template can create any number of output files. Use a define construct to create an output file. The file name is specified as an argument to define, and everything inside the define block up to the matching end is written as the contents of that file.

```
{{ define "/var/lib/haproxy/conf/haproxy.config" }}
global
{{ end }}
```

The above will copy global to the /var/lib/haproxy/conf/haproxy.config file, and then close the file.

Set up logging based on environment variables.

```
{{ with (env "ROUTER_SYSLOG_ADDRESS" "") }}
  log {{.}} {{env "ROUTER_LOG_FACILITY" "local1"}} {{env "ROUTER_LOG_LEVEL" "warning"}}
{{ end }}
```

The **env** function extracts the value for the environment variable. If the environment variable is not defined or **nil**, the second argument is returned.

The with construct sets the value of "." (dot) within the with block to whatever value is provided as an argument to with. The with action tests Dot for nil. If not nil, the clause is processed up to the end. In the above, assume ROUTER_SYSLOG_ADDRESS contains /var/log/msg, ROUTER_LOG_FACILITY is not defined, and ROUTER_LOG_LEVEL contains info. The following will be copied to the output file:

```
log /var/log/msg local1 info
```

Each admitted route ends up generating lines in the configuration file. Use **range** to go through the admitted routes:

```
{{ range $cfgIdx, $cfg := .State }}
backend be_http_{{$cfgIdx}}
{{end}}
```

.State is a map of ServiceAliasConfig, where the key is the route name. range steps through the map and, for each pass, it sets \$cfgIdx with the key, and sets `\$cfg to point to the

ServiceAliasConfig that describes the route. If there are two routes named myroute and hisroute, the above will copy the following to the output file:

```
backend be_http_myroute
backend be_http_hisroute
```

Route Annotations, **\$cfg.Annotations**, is also a map with the annotation name as the key and the content string as the value. The route can have as many annotations as desired and the use is defined by the template author. The user codes the annotation into the route and the template author customized the HAProxy template to handle the annotation.

The common usage is to index the annotation to get the value.

```
{{$balanceAlgo := index $cfg.Annotations "haproxy.router.openshift.io/balance"}}
```

The index extracts the value for the given annotation, if any. Therefore, `\$balanceAlgo will contain the string associated with the annotation or nil. As above, you can test for a non- nil string and act on it with the with construct.

```
{{ with $balanceAlgo }}
 balance $balanceAlgo
{{ end }}
```

Here when \$balanceAlgo is not nil, balance \$balanceAlgo is copied to the output file.

In a second example, you want to set a server timeout based on a timeout value set in an annotation.

```
$value := index $cfg.Annotations "haproxy.router.openshift.io/timeout"
```

The **\$value** can now be evaluated to make sure it contains a properly constructed string. The **matchPattern** function accepts a regular expression and returns **true** if the argument satisfies the expression.

```
matchPattern "[1-9][0-9]*(us\|ms\|s\|m\|h\|d)?" $value
```

This would accept 5000ms but not 7y. The results can be used in a test.

```
{{if (matchPattern "[1-9][0-9]*(us\|ms\|s\|m\|h\|d)?" $value) }}
timeout server {{$value}}
{{ end }}
```

It can also be used to match tokens:

```
matchPattern "roundrobin|leastconn|source" $balanceAlgo
```

Alternatively matchValues can be used to match tokens:

```
matchValues $balanceAlgo "roundrobin" "leastconn" "source"
```

4.3.4. Using a ConfigMap to Replace the Router Configuration Template

You can use a ConfigMap to customize the router instance without rebuilding the router image. The *haproxy-config.template*, *reload-haproxy*, and other scripts can be modified as well as creating and modifying router environment variables.

- 1. Copy the *haproxy-config.template* that you want to modify as described above. Modify it as desired.
- 2. Create a ConfigMap:

```
\$ oc create configmap customrouter --from-file=haproxy-config.template
```

The customrouter ConfigMap now contains a copy of the modified *haproxy-config.template* file.

3. Modify the router deployment configuration to mount the ConfigMap as a file and point the TEMPLATE_FILE environment variable to it. This can be done via oc set env and oc volume commands, or alternatively by editing the router deployment configuration.

Using oc commands

Editing the Router Deployment Configuration

Use oc edit dc router to edit the router deployment configuration with a text editor.

```
- name: STATS_USERNAME
          value: admin
        - name: TEMPLATE_FILE 1
          value: /var/lib/haproxy/conf/custom/haproxy-
config.template
        image: openshift/origin-haproxy-routerp
        terminationMessagePath: /dev/termination-log
        volumeMounts: 2
        - mountPath: /var/lib/haproxy/conf/custom
          name: config-volume
      dnsPolicy: ClusterFirst
      terminationGracePeriodSeconds: 30
     volumes: 3
      - configMap:
          name: customrouter
        name: config-volume
  test: false
```

- In the spec.container.env field, add the TEMPLATE_FILE environment variable to point to the mounted *haproxy-config.template* file.
- Add the spec.container.volumeMounts field to create the mount point.
- 3 Add a new spec.volumes field to mention the ConfigMap.

Save the changes and exit the editor. This restarts the router.

4.3.5. Using Stick Tables

The following example customization can be used in a highly-available routing setup to use stick-tables that synchronize between peers.

Adding a Peer Section

In order to synchronize stick-tables amongst peers you must a define a peers section in your HAProxy configuration. This section determines how HAProxy will identify and connect to peers. The plug-in provides data to the template under the .PeerEndpoints variable to allow you to easily identify members of the router service. You may add a peer section to the haproxy-config.template file inside the router image by adding:

```
{{ if (len .PeerEndpoints) gt 0 }}
peers openshift_peers
  {{ range $endpointID, $endpoint := .PeerEndpoints }}
  peer {{$endpoint.TargetName}} {{$endpoint.IP}}:1937
  {{ end }}
{{ end }}
```

Changing the Reload Script

When using stick-tables, you have the option of telling HAProxy what it should consider the name of the local host in the peer section. When creating endpoints, the plug-in attempts to set the TargetName to the value of the endpoint's TargetRef.Name. If TargetRef is not set, it will set the TargetName to the IP address. The TargetRef.Name corresponds with the Kubernetes host name, therefore you can add the -L option to the reload-haproxy script to identify the local host in the peer section.

```
peer_name=$HOSTNAME 1

if [ -n "$old_pid" ]; then
   /usr/sbin/haproxy -f $config_file -p $pid_file -L $peer_name -sf
$old_pid
else
   /usr/sbin/haproxy -f $config_file -p $pid_file -L $peer_name
fi
```

Must match an endpoint target name that is used in the peer section.

Modifying Back Ends

Finally, to use the stick-tables within back ends, you can modify the HAProxy configuration to use the stick-tables and peer set. The following is an example of changing the existing back end for TCP connections to use stick-tables:

```
{{ if eq $cfg.TLSTermination "passthrough" }}
backend be_tcp_{{$cfgIdx}}
balance leastconn
timeout check 5000ms
stick-table type ip size 1m expire 5m{{ if (len $.PeerEndpoints) gt 0 }}
peers openshift_peers {{ end }}
stick on src
{{ range $endpointID, $endpoint :=
$serviceUnit.EndpointTable }}
server {{$endpointID}} {{$endpoint.IP}}:{{$endpoint.Port}} check inter
5000ms
{{ end }}
{{ end }}
```

After this modification, you can rebuild your router.

4.3.6. Rebuilding Your Router

In order to rebuild the router, you need copies of several files that are present on a running router. Make a work directory and copy the files from the router:

```
# mkdir - myrouter/conf
# cd myrouter
# oc get po
NAME
                           READY
                                     STATUS
                                               RESTARTS
                                                          AGE
router-2-40fc3
                           1/1
                                     Running
                                                           11d
# oc rsh router-2-40fc3 cat haproxy-config.template > conf/haproxy-
config.template
# oc rsh router-2-40fc3 cat error-page-503.http > conf/error-page-503.http
# oc rsh router-2-40fc3 cat default_pub_keys.pem >
conf/default_pub_keys.pem
# oc rsh router-2-40fc3 cat ../Dockerfile > Dockerfile
# oc rsh router-2-40fc3 cat ../reload-haproxy > reload-haproxy
```

You can edit or replace any of these files. However, *conf/haproxy-config.template* and *reload-haproxy* are the most likely to be modified.

After updating the files:

```
# docker build -t openshift/origin-haproxy-router-myversion .
# docker tag openshift/origin-haproxy-router-myversion
172.30.243.98:5000/openshift/haproxy-router-myversion 1
# docker push 172.30.243.98:5000/openshift/origin-haproxy-router-pc:latest
2
```

- Tag the version with the repository. In this case the repository is 172.30.243.98:5000.
- Push the tagged version to the repository. It may be necessary to **docker login** to the repository first.

To use the new router, edit the router deployment configuration either by changing the image: string or by adding the --images=<repo>/<image>:<tag> flag to the oadm router command.

When debugging the changes, it is helpful to set imagePullPolicy: Always in the deployment configuration to force an image pull on each pod creation. When debugging is complete, you can change it back to imagePullPolicy: IfNotPresent to avoid the pull on each pod start.

4.4. CONFIGURING THE HAPROXY ROUTER TO USE THE PROXY PROTOCOL

4.4.1. Overview

By default, the HAProxy router expects incoming connections to unsecure, edge, and re-encrypt routes to use HTTP. However, you can configure the router to expect incoming requests by using the PROXY protocol instead. This topic describes how to configure the HAProxy router and an external load balancer to use the PROXY protocol.

4.4.2. Why Use the PROXY Protocol?

When an intermediary service such as a proxy server or load balancer forwards an HTTP request, it appends the source address of the connection to the request's "Forwarded" header in order to provide this information to subsequent intermediaries and to the back-end service to which the request is ultimately forwarded. However, if the connection is encrypted, intermediaries cannot modify the "Forwarded" header. In this case, the HTTP header will not accurately communicate the original source address when the request is forwarded.

To solve this problem, some load balancers encapsulate HTTP requests using the PROXY protocol as an alternative to simply forwarding HTTP. Encapsulation enables the load balancer to add information to the request without modifying the forwarded request itself. In particular, this means that the load balancer can communicate the source address even when forwarding an encrypted connection.

The HAProxy router can be configured to accept the PROXY protocol and decapsulate the HTTP request. Because the router terminates encryption for edge and re-encrypt routes, the router can then update the "Forwarded" HTTP header (and related HTTP headers) in the request, appending any source address that is communicated using the PROXY protocol.

WARNING

The PROXY protocol and HTTP are incompatible and cannot be mixed. If you use a load balancer in front of the router, both must use either the PROXY protocol or HTTP. Configuring one to use one protocol and the other to use the other protocol will cause routing to fail.

4.4.3. Using the PROXY Protocol

By default, the HAProxy router does not use the PROXY protocol. The router can be configured using the **ROUTER_USE_PROXY_PROTOCOL** environment variable to expect the PROXY protocol for incoming connections:

Enable the PROXY Protocol

\$ oc env dc/router ROUTER_USE_PROXY_PROTOCOL=true

Set the variable to any value other than true or TRUE to disable the PROXY protocol:

Disable the PROXY Protocol

 $\$ oc env dc/router ROUTER_USE_PROXY_PROTOCOL=false

If you enable the PROXY protocol in the router, you must configure your load balancer in front of the router to use the PROXY protocol as well. Following is an example of configuring Amazon's Elastic Load Balancer (ELB) service to use the PROXY protocol. This example assumes that ELB is forwarding ports 80 (HTTP), 443 (HTTPS), and 5000 (for the image registry) to the router running on one or more EC2 instances.

Configure Amazon ELB to Use the PROXY Protocol

1. To simplify subsequent steps, first set some shell variables:

```
$ lb='infra-lb' 1
$ instances=( 'i-079b4096c654f563c' ) 2
$ secgroups=( 'sg-e1760186' ) 3
$ subnets=( 'subnet-cf57c596' ) 4
```

- The name of your ELB.
- The instance or instances on which the router is running.
- The security group or groups for this ELB.
- The subnet or subnets for this ELB.
- 2. Next, create the ELB with the appropriate listeners, security groups, and subnets.

NOTE

You must configure all listeners to use the TCP protocol, not the HTTP protocol.

```
{
    "DNSName": "infra-lb-2006263232.us-east-1.elb.amazonaws.com"
}
```

3. Register your router instance or instances with the ELB:

4. Configure the ELB's health check:

```
$ aws elb configure-health-check --load-balancer-name "$lb" \
    --health-check
'Target=HTTP:1936/healthz,Interval=30,UnhealthyThreshold=2,HealthyTh
reshold=2,Timeout=5'
{
    "HealthCheck": {
        "HealthyThreshold": 2,
        "Interval": 30,
        "Target": "HTTP:1936/healthz",
        "Timeout": 5,
        "UnhealthyThreshold": 2
    }
}
```

5. Finally, create a load-balancer policy with the **ProxyProtocol** attribute enabled, and configure it on the ELB's TCP ports 80 and 443:

```
$ aws elb create-load-balancer-policy --load-balancer-name "$lb" \
     --policy-name "${lb}-ProxyProtocol-policy" \
     --policy-type-name 'ProxyProtocolPolicyType' \
     --policy-attributes
'AttributeName=ProxyProtocol, AttributeValue=true'
$ for port in 80 443
    do
     aws elb set-load-balancer-policies-for-backend-server \
     --load-balancer-name "$lb" \
     --instance-port "$port" \
     --policy-names "${lb}-ProxyProtocol-policy"
    done
```

Verify the Configuration

You can examine the load balancer as follows to verify that the configuration is correct:

```
$ aws elb describe-load-balancers --load-balancer-name "$lb" |
   jq '.LoadBalancerDescriptions| [.[]|.ListenerDescriptions]'
```

```
"Listener": {
      "InstancePort": 80,
      "LoadBalancerPort": 80,
      "Protocol": "TCP",
      "InstanceProtocol": "TCP"
    "PolicyNames": ["infra-lb-ProxyProtocol-policy"] 1
 },
  {
    "Listener": {
      "InstancePort": 443,
      "LoadBalancerPort": 443,
      "Protocol": "TCP",
      "InstanceProtocol": "TCP"
    },
    "PolicyNames": ["infra-lb-ProxyProtocol-policy"] 2
 },
    "Listener": {
      "InstancePort": 5000,
      "LoadBalancerPort": 5000,
      "Protocol": "TCP",
      "InstanceProtocol": "TCP"
    "PolicyNames": [] 3
 }
]
```

- The listener for TCP port 80 should have the policy for using the PROXY protocol.
- The listener for TCP port 443 should have the same policy.
- The listener for TCP port 5000 should **not** have the policy.

Alternatively, if you already have an ELB configured, but it is not configured to use the PROXY protocol, you will need to change the existing listener for TCP port 80 to use the TCP protocol instead of HTTP (TCP port 443 should already be using the TCP protocol):

```
$ aws elb delete-load-balancer-listeners --load-balancer-name "$lb" \
    --load-balancer-ports 80
$ aws elb create-load-balancer-listeners --load-balancer-name "$lb" \
    --listeners
'Protocol=TCP, LoadBalancerPort=80, InstanceProtocol=TCP, InstancePort=80'
```

Verify the Protocol Updates

Verify that the protocol has been updated as follows:

```
$ aws elb describe-load-balancers --load-balancer-name "$lb" |
    jq '[.LoadBalancerDescriptions[]|.ListenerDescriptions]'
    [
```

```
{
    "Listener": {
      "InstancePort": 443,
      "LoadBalancerPort": 443,
      "Protocol": "TCP",
      "InstanceProtocol": "TCP"
    },
    "PolicyNames": []
 },
    "Listener": {
      "InstancePort": 5000,
      "LoadBalancerPort": 5000,
      "Protocol": "TCP",
      "InstanceProtocol": "TCP"
    "PolicyNames": []
 },
    "Listener": {
      "InstancePort": 80,
      "LoadBalancerPort": 80,
      "Protocol": "TCP", 1
      "InstanceProtocol": "TCP"
    "PolicyNames": []
]
```

All listeners, including the listener for TCP port 80, should be using the TCP protocol.

Then, create a load-balancer policy and add it to the ELB as described in Step 5 above.

4.5. USING THE F5 ROUTER PLUG-IN

4.5.1. Overview

NOTE

The F5 router plug-in is available starting in OpenShift Container Platform 3.0.2.

The F5 router plug-in is provided as a container image and run as a pod, just like the default HAProxy router.

IMPORTANT

Support relationships between F5 and Red Hat provide a full scope of support for F5 integration. F5 provides support for the **F5 BIG-IP®** product. Both F5 and Red Hat jointly support the integration with Red Hat OpenShift. While Red Hat helps with bug fixes and feature enhancements, all get communicated to F5 Networks where they are managed as part of their development cycles.

4.5.2. Prerequisites and Supportability

When deploying the F5 router plug-in, ensure you meet the following requirements:

- A F5 host IP with:
 - o Credentials for API access
 - SSH access via a private key
- A virtual server for HTTP routes:
 - HTTP profile must be http.
- A virtual server with HTTP profile routes:
 - o HTTP profile must be http
 - o SSL Profile (client) must be clientssl
 - SSL Profile (server) must be serverss!
- For edge integration (not recommended):
 - A working ramp node
 - o A working tunnel to the ramp node
- For native integration:
 - o A host-internal IP capable of communicating with all nodes on the port 4789/UDP
 - o The sdn-services add-on license installed on the F5 host.

OpenShift Container Platform supports only the following F5 BIG-IP® versions:

- 11.x
- 12.x

However, the following features are not supported with F5 BIG-IP®: * Idling applications * Re-ecrypt routes * Unencrypted HTTP traffic in allow and redirect mode, with edge TLS termination * Certificates specifically configured for particular routes

4.5.2.1. Configuring the Virtual Servers

As a prerequisite to working with the **openshift-F5** integrated router, two virtual servers (one virtual server each for HTTP and HTTPS profiles, respectively) need to be set up in the **F5 BIG-IP**® appliance.

To set up a virtual server in the F5 BIG-IP® appliance, follow the instructions from F5.

While creating the virtual server, ensure the following settings are in place:

- For the HTTP server, set the ServicePort to 'http'/80.
- For the HTTPS server, set the ServicePort to 'https'/443.

- In the basic configuration, set the HTTP profile to /Common/http for both of the virtual servers.
- For the HTTPS server, create a default client-ssl profile and select it for the SSL Profile (Client).
 - To create the default client SSL profile, follow the instructions from F5, especially the
 Configuring the fallback (default) client SSL profile section, which discusses that the
 certificate/key pair is the default that will be served in the case that custom certificates
 are not provided for a route or server name.

4.5.3. Deploying the F5 Router

IMPORTANT

The F5 router must be run in privileged mode, because route certificates are copied using the scp command:

```
$ oc adm policy remove-scc-from-user hostnetwork -z router
$ oc adm policy add-scc-to-user privileged -z router
```

Deploy the F5 router with the oadm router command, but provide additional flags (or environment variables) specifying the following parameters for the F5 BIG-IP® host:

Flag	Description
type=f5- router	Specifies that an F5 router should be launched (the defaulttype is haproxy-router).
external- host	Specifies the F5 BIG-IP ® host's management interface's host name or IP address.
external- host- username	Specifies the F5 BIG-IP® user name (typically admin).
external- host- password	Specifies the F5 BIG-IP® password.
external- host-http- vserver	Specifies the name of the F5 virtual server for HTTP connections. This must be configured by the user prior to launching the router pod.
external- host-https- vserver	Specifies the name of the F5 virtual server for HTTPS connections. This must be configured by the user prior to launching the router pod.
external- host- private-key	Specifies the path to the SSH private key file for the F5 BIG-IP® host. Required to upload and delete key and certificate files for routes.

Flag	Description
external- host- insecure	A Boolean flag that indicates that the F5 router should skip strict certificate verification with the F5 BIG-IP® host.
external- host- partition- path	Specifies the F5 BIG-IP® partition path (the default is/Common).

For example:

```
$ oadm router \
    --type=f5-router \
    --external-host=10.0.0.2 \
    --external-host-username=admin \
    --external-host-password=mypassword \
    --external-host-http-vserver=ose-vserver \
    --external-host-https-vserver=https-ose-vserver \
    --external-host-private-key=/path/to/key \
    --host-network=false \
    --service-account=router
```

As with the HAProxy router, the oadm router command creates the service and deployment configuration objects, and thus the replication controllers and pod(s) in which the F5 router itself runs. The replication controller restarts the F5 router in case of crashes. Because the F5 router is watching routes, endpoints, and nodes and configuring F5 BIG-IP® accordingly, running the F5 router in this way, along with an appropriately configured F5 BIG-IP® deployment, should satisfy high-availability requirements.

4.5.4. F5 Router Partition Paths

Partition paths allow you to store your OpenShift Container Platform routing configuration in a custom F5 BIG-IP® administrative partition, instead of the default /Common partition. You can use custom administrative partitions to secure F5 BIG-IP® environments. This means that an OpenShift Container Platform-specific configuration stored in F5 BIG-IP® system objects reside within a logical container, allowing administrators to define access control policies on that specific administrative partition.

See the F5 BIG-IP® documentation for more information about administrative partitions.

Use the --external-host-partition-path flag when deploying the F5 router to specify a partition path:

```
$ oadm router --external-host-partition-path=/0penShift/zone1 ...
```

4.5.5. Setting Up F5 Native Integration

NOTE

This section reviews how to set up F5 native integration with OpenShift Container Platform. The concepts of F5 appliance and OpenShift Container Platform connection and data flow of F5 native integration are discussed in the F5 Native Integration section of the Routes topic.

NOTE

Only **F5 BIG-IP**® appliance version 12.x and above works with the native integration presented in this section. You also need sdn-services add-on license for the integration to work properly. For version 11.x, follow the instructions to set up a *ramp node*.

As of OpenShift Container Platform version 3.4, using native integration of F5 with OpenShift Container Platform does not require configuring a ramp node for F5 to be able to reach the pods on the overlay network as created by OpenShift SDN.

The F5 controller pod needs to be launched with enough information so that it can successfully directly connect to pods.

1. Create a ghost host subnet on the OpenShift Container Platform cluster:

```
$ cat > f5-hostsubnet.yaml << EOF
{
    "kind": "HostSubnet",
    "apiVersion": "v1",
    "metadata": {
        "name": "openshift-f5-node",
        "annotations": {
        "pod.network.openshift.io/assign-subnet": "true",
    "pod.network.openshift.io/fixed-vnid-host": "0"
        }
     },
     "host": "openshift-f5-node",
     "hostIP": "10.3.89.213"
} EOF
$ oc create -f f5-hostsubnet.yaml</pre>
```

- Make F5 global.
- The internal IP of the F5 appliance.
- 2. Determine the subnet allocated for the ghost **hostsubnet** just created:

\$ oc get hostsubnets		
NAME	HOST	HOST IP
SUBNET		
openshift-f5-node	openshift-f5-node	10.3.89.213
10.131.0.0/23		
openshift-master-node	openshift-master-node	172.17.0.2
10.129.0.0/23		
openshift-node-1	openshift-node-1	172.17.0.3

```
10.128.0.0/23
openshift-node-2 openshift-node-2 172.17.0.4
10.130.0.0/23
```

- 3. Check the SUBNET for the newly created host subnet. In this example, 10.131.0.0/23.
- 4. Get the entire pod network's CIDR:

```
$ oc get clusternetwork
```

This value will be something like 10.128.0.0/14, noting the mask (14 in this example).

- 5. To construct the gateway address, pick any IP address from the **hostsubnet** (for example, 10.131.0.5). Use the mask of the pod network (14). The gateway address becomes: 10.131.0.5/14.
- 6. Launch the F5 controller pod, following these instructions. Additionally, allow the access to 'node' cluster resource for the service account and use the two new additional options for VXLAN native integration.

```
$ # Add policy to allow router to access nodes using the sdn-reader
role
$ oadm policy add-cluster-role-to-user system:sdn-reader
system:serviceaccount:default:router
$ # Launch the router pod with vxlan-gw and F5's internal IP as
extra arguments
$ #--external-host-internal-ip=10.3.89.213
$ #--external-host-vxlan-gw=10.131.0.5/14
$ oadm router \
    --type=f5-router \
    --external-host=10.3.89.90 \
    --external-host-username=admin \
    --external-host-password=mypassword \
    --external-host-http-vserver=ose-vserver \
    --external-host-https-vserver=https-ose-vserver \
    --external-host-private-key=/path/to/key \
    --credentials='/etc/openshift/master/openshift-
router.kubeconfig' \
    --service-account=router \
    --host-network=false \
    --external-host-internal-ip=10.3.89.213 \
    --external-host-vxlan-gw=10.131.0.5/14
```

The F5 setup is now ready, without the need to set up the ramp node.

CHAPTER 5. UPGRADING A CLUSTER

5.1. OVERVIEW

When new versions of OpenShift Container Platform are released, you can upgrade your existing cluster to apply the latest enhancements and bug fixes. This includes upgrading from previous minor versions, such as release 3.4 to 3.5, and applying asynchronous errata updates within a minor version (3.5.z releases). See the OpenShift Container Platform 3.5 Release Notes to review the latest changes.

NOTE

Due to the core architectural changes between the major versions, OpenShift Enterprise 2 environments cannot be upgraded to OpenShift Container Platform 3 and require a fresh installation.

Unless noted otherwise, node and masters within a major version are forward and backward compatible across one minor version, so upgrading your cluster should go smoothly. However, you should not run mismatched versions longer than necessary to upgrade the entire cluster.

5.1.1. In-place or Blue-Green Upgrades

There are two methods for performing OpenShift Container Platform cluster upgrades. You can either do in-place upgrades (automated or manual), or upgrade using a blue-green deployment method.

In-place Upgrades

With in-place upgrades, the cluster upgrade is performed on all hosts in a single, running cluster: first masters and then nodes. Pods are evacuated off of nodes and recreated on other running nodes before a node upgrade begins; this helps reduce downtime of user applications.

If you installed using the quick or advanced installation and the ~/.config/openshift/installer.cfg.yml or inventory file that was used is available, you can perform an automated in-place upgrade.

Alternatively, you can upgrade in-place manually.

Blue-green Deployments

The blue-green deployment upgrade method follows a similar flow to the in-place method: masters and etcd servers are still upgraded first, however a parallel environment is created for new nodes instead of upgrading them in-place.

This method allows administrators to switch traffic from the old set of nodes (e.g., the "blue" deployment) to the new set (e.g., the "green" deployment) after the new deployment has been verified. If a problem is detected, it is also then easy to rollback to the old deployment quickly.

5.2. PERFORMING AUTOMATED IN-PLACE CLUSTER UPGRADES

5.2.1. Overview

IMPORTANT

An etcd performance issue has been discovered on new and upgraded OpenShift Container Platform 3.5 clusters. See the following Knowledgebase Solution for further details:

https://access.redhat.com/solutions/2916381 (BZ#1415839)

If you installed using the advanced installation and the inventory file that was used is available, you can use the upgrade playbook to automate the OpenShift cluster upgrade process. If you installed using the quick installation method and a ~/.config/openshift/installer.cfg.yml file is available, you can use the installer to perform the automated upgrade.

The automated upgrade performs the following steps for you:

- Applies the latest configuration.
- Upgrades master and etcd components and restarts services.
- Upgrades node components and restarts services.
- Applies the latest cluster policies.
- Updates the default router if one exists.
- Updates the default registry if one exists.
- Updates default image streams and InstantApp templates.

IMPORTANT

Ensure that you have met all prerequisites before proceeding with an upgrade. Failure to do so can result in a failed upgrade.

5.2.2. Preparing for an Automated Upgrade

IMPORTANT

Before upgrading your cluster to OpenShift Container Platform 3.5, the cluster must be already upgraded to the latest asynchronous release of version 3.4. Cluster upgrades cannot span more than one minor version at a time, so if your cluster is at a version earlier than 3.4, you must first upgrade incrementally (e.g., 3.2 to 3.3, then 3.3 to 3.4).

NOTE

Before attempting the upgrade, follow the steps in Verifying the Upgrade to verify the cluster's health. This will confirm that nodes are in the Ready state, running the expected starting version, and will ensure that there are no diagnostic errors or warnings.

To prepare for an automated upgrade:

1. If you are upgrading from OpenShift Container Platform 3.4 to 3.5, manually disable the 3.4 channel and enable the 3.5 channel on each master and node host:

2. For any upgrade path, always ensure that you have the latest version of the **atomic-openshift-utils** package on each RHEL 7 system, which also updates the **openshift-ansible-*** packages:

```
# yum update atomic-openshift-utils
```

3. Install or update to the following latest available *-excluder packages on each RHEL 7 system, which helps ensure your systems stay on the correct versions of atomic-openshift and docker packages when you are not trying to upgrade, according to the OpenShift Container Platform version:

```
# yum install atomic-openshift-excluder atomic-openshift-docker-
excluder
```

These packages add entries to the exclude directive in the host's /etc/yum.conf file.

4. You must be logged in as a cluster administrative user on the master host for the upgrade to succeed:

```
$ oc login
```

After satisfying these steps, there are two methods for running the automated upgrade:

- Using the installer
- Running the upgrade playbook directly

Choose and follow one of these methods.

5.2.3. Using the Installer to Upgrade

If you installed OpenShift Container Platform using the quick installation method, you should have an installation configuration file located at ~/.config/openshift/installer.cfg.yml. The installer requires this file to start an upgrade.

The installer supports upgrading between minor versions of OpenShift Container Platform (one minor version at a time, e.g., 3.4 to 3.5) as well as between asynchronous errata updates within a minor version (e.g., 3.5.z).

If you have an older format installation configuration file in ~/.config/openshift/installer.cfg.yml from an installation of a previous cluster version, the installer will attempt to upgrade the file to the new supported format. If you do not have an installation configuration file of any format, you can create one manually.

To start an upgrade with the quick installer:

1. Satisfy the steps in Preparing for an Automated Upgrade to ensure you are using the latest upgrade playbooks.

2. Run the installer with the upgrade subcommand:

atomic-openshift-installer upgrade

- 3. Then, follow the on-screen instructions to upgrade to the latest release.
- 4. After all master and node upgrades have completed, a recommendation will be printed to reboot all hosts. After rebooting, if there are no additional features enabled, you can verify the upgrade. Otherwise, the next step depends on what additional features have you previously enabled.

Feature	Next Step
Aggregated Logging	Upgrade the EFK logging stack.
Cluster Metrics	Upgrade cluster metrics.

5.2.4. Running Upgrade Playbooks Directly

You can run automated upgrade playbooks using Ansible directly, similar to the advanced installation method, if you have an inventory file. Playbooks can be run using the ansible-playbook command.

The same $v3_5$ upgrade playbooks can be used for either of the following scenarios:

- Upgrading existing OpenShift Container Platform 3.4 clusters to 3.5
- Upgrading existing OpenShift Container Platform 3.5 clusters to the latest asynchronous errata updates

5.2.4.1. Upgrading the Control Plane and Nodes in Separate Phases

An OpenShift Container Platform cluster can be upgraded in one or more phases. You can choose whether to upgrade all hosts in one phase by running a single Ansible playbook, or upgrade the *control plane* (master components) and nodes in multiple phases using separate playbooks.

NOTE

Instructions on the full upgrade process and when to call these playbooks are described in Upgrading to the Latest OpenShift Container Platform 3.5 Release .

When upgrading in separate phases, the control plane phase includes upgrading:

- etcd
- master components
- node services running on masters
- Docker running on masters
- Docker running on any stand-alone etcd hosts

When upgrading only the nodes, the control plane must already be upgraded. The node phase includes upgrading:

- node services running on stand-alone nodes
- Docker running on stand-alone nodes

NOTE

Nodes running master components are not included during the node upgrade phase, even though they have node services and Docker running on them. Instead, they are upgraded as part of the control plane upgrade phase. This ensures node services and Docker on masters are not upgraded twice (once during the control plane phase and again during the node phase).

5.2.4.2. Customizing Node Upgrades

Whether upgrading in a single or multiple phases, you can customize how the node portion of the upgrade progresses by passing certain Ansible variables to an upgrade playbook using the -e option.

NOTE

Instructions on the full upgrade process and when to call these playbooks are described in Upgrading to the Latest OpenShift Container Platform 3.5 Release.

The **openshift_upgrade_nodes_serial** variable can be set to an integer or percentage to control how many node hosts are upgraded at the same time. The default is **1**, upgrading nodes one at a time.

For example, to upgrade 20 percent of the total number of detected nodes at a time:

```
$ ansible-playbook -i <path/to/inventory/file> \
      </path/to/upgrade/playbook> \
      -e openshift_upgrade_nodes_serial="20%"
```

The openshift_upgrade_nodes_label variable allows you to specify that only nodes with a certain label are upgraded. This can also be combined with the openshift_upgrade_nodes_serial variable.

For example, to only upgrade nodes in the **group1** region, two at a time:

```
$ ansible-playbook -i <path/to/inventory/file> \
    </path/to/upgrade/playbook> \
    -e openshift_upgrade_nodes_serial="2" \
    -e openshift_upgrade_nodes_label="region=group1"
```

See Managing Nodes for more on node labels.

5.2.4.3. Customizing Upgrades With Ansible Hooks

When upgrading OpenShift Container Platform, you can execute custom tasks during specific operations through a system called *hooks*. Hooks allow cluster administrators to provide files defining tasks to execute before and/or after specific areas during installations and upgrades. This can be very helpful to validate or modify custom infrastructure when installing or upgrading OpenShift Container Platform.

It is important to remember that when a hook fails, the operation fails. This means a good hook can run multiple times and provide the same results. A great hook is idempotent.

5.2.4.3.1. Limitations

- Hooks have no defined or versioned interface. They can use internal openshift-ansible
 variables, but there is no guarantee these will remain in future releases. In the future, hooks
 may be versioned, giving you advance warning that your hook needs to be updated to work
 with the latest openshift-ansible.
- Hooks have no error handling, so an error in a hook will halt the upgrade process. The problem will need to be addressed and the upgrade re-run.

5.2.4.3.2. Using Hooks

Hooks are defined in the *hosts* inventory file under the **OSEv3:vars** section.

Each hook must point to a YAML file which defines Ansible tasks. This file will be used as an *include*, meaning that the file cannot be a playbook, but a set of tasks. Best practice suggests using absolute paths to the hook file to avoid any ambiguity.

Example Hook Definitions in an Inventory File

```
[OSEv3:vars]
openshift_master_upgrade_pre_hook=/usr/share/custom/pre_master.yml
openshift_master_upgrade_hook=/usr/share/custom/master.yml
openshift_master_upgrade_post_hook=/usr/share/custom/post_master.yml
```

Example pre_master.yml Task

```
# Trivial example forcing an operator to ack the start of an upgrade
# file=/usr/share/custom/pre_master.yml

- name: note the start of a master upgrade
  debug:
    msg: "Master upgrade of {{ inventory_hostname }} is about to start"

- name: require an operator agree to start an upgrade
  pause:
    prompt: "Hit enter to start the master upgrade"
```

5.2.4.3.3. Available Upgrade Hooks

openshift_master_upgrade_pre_hook

- Runs before each master is upgraded.
- This hook runs against each master in serial.
- If a task must run against a different host, said task must use delegate_to or local_action.

openshift_master_upgrade_hook

- Runs after each master is upgraded, but before its service or system restart.
- This hook runs against **each master** in serial.
- If a task must run against a different host, said task must use delegate_to or local action.

openshift_master_upgrade_post_hook

- Runs after each master is upgraded and has had its service or system restart.
- This hook runs against each master in serial.
- If a task must run against a different host, said task must use **delegate_to** or **local_action**.

5.2.4.4. Upgrading to the Latest OpenShift Container Platform 3.5 Release

To upgrade an existing OpenShift Container Platform 3.4 or 3.5 cluster to the latest 3.5 release:

- 1. Satisfy the steps in Preparing for an Automated Upgrade to ensure you are using the latest upgrade playbooks.
- 2. Ensure the deployment_type parameter in your inventory file is set to openshift-enterprise.
- 3. If you have multiple masters configured and want to enable rolling, full system restarts of the hosts, you can set the openshift_rolling_restart_mode parameter in your inventory file to system. Otherwise, the default value services performs rolling service restarts on HA masters, but does not reboot the systems. See Configuring Cluster Variables for details.
- 4. At this point, you can choose to run the upgrade in a single or multiple phases. See Upgrading the Control Plane and Nodes in Separate Phases for more details which components are upgraded in each phase.

If your inventory file is located somewhere other than the default /etc/ansible/hosts, add the -i flag to specify its location. If you previously used the atomic-openshift-installer command to run your installation, you can check ~/.config/openshift/hosts for the last inventory file that was used, if needed.

NOTE

You can add --tags pre_upgrade to the following ansible-playbook commands to run the pre-upgrade checks for the playbook. This is a dry-run option that preforms all pre-upgrade checks without actually upgrading any hosts, and reports any problems found.

Option A) Upgrade control plane and nodes in a single phase.
 Run the upgrade.yml playbook to upgrade the cluster in a single phase using one playbook; the control plane is still upgraded first, then nodes in-place:

ansible-playbook -i </path/to/inventory/file> \
 /usr/share/ansible/openshift-ansible/playbooks/byo/openshiftcluster/upgrades/v3_5/upgrade.yml \

- [-e <customized_node_upgrade_variables>] 1
- See Customizing Node Upgrades for any desired <customized_node_upgrade_variables>.
- Option B) Upgrade the control plane and nodes in separate phases.
 - a. To upgrade only the control plane, run the *upgrade_control_plane.yaml* playbook:

```
# ansible-playbook -i </path/to/inventory/file> \
    /usr/share/ansible/openshift-
ansible/playbooks/byo/openshift-
cluster/upgrades/v3_5/upgrade_control_plane.yml
```

b. To upgrade only the nodes, run the *upgrade_nodes.yaml* playbook:

```
# ansible-playbook -i </path/to/inventory/file> \
    /usr/share/ansible/openshift-
ansible/playbooks/byo/openshift-
cluster/upgrades/v3_5/upgrade_nodes.yml \
    [-e <customized_node_upgrade_variables>] 1
```

See Customizing Node Upgrades for any desired <customized_node_upgrade_variables>.

If you are upgrading the nodes in groups as described in Customizing Node Upgrades, continue invoking the *upgrade_nodes.yml* playbook until all nodes have been successfully upgraded.

 After all master and node upgrades have completed, a recommendation will be printed to reboot all hosts. After rebooting, if there are no additional features enabled, you can verify the upgrade. Otherwise, the next step depends on what additional features have you previously enabled.

Feature	Next Step
Aggregated Logging	Upgrade the EFK logging stack.
Cluster Metrics	Upgrade cluster metrics.

5.2.5. Upgrading the EFK Logging Stack

To upgrade an existing EFK logging stack deployment, you must use the provided /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-cluster/openshift-logging.yml Ansible playbook. This is the playbook to use if you were deploying logging for the first time on an existing cluster, but is also used to upgrade existing logging deployments.

 If you have not already done so, see Specifying Logging Ansible Variables in the Aggregating Container Logs topic and update your Ansible inventory file to at least set the following required variable within the [OSEv3:vars] section: [OSEv3:vars]
openshift_logging_install_logging=true 1
openshift_logging_image_version=<tag> 2

- Enables the ability to upgrade the logging stack.
- 2 Replace <tag> with v3.5 for the latest version.
- 2. Add any other **openshift_logging_*** variables that you want to specify to override the defaults, as described in Specifying Logging Ansible Variables.
- 3. When you have finished updating your inventory file, follow the instructions in Deploying the EFK Stack to run the *openshift-logging.yml* playbook and complete the logging deployment upgrade.

5.2.6. Upgrading Cluster Metrics

To upgrade an existing cluster metrics deployment, you must use the provided /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-cluster/openshift-metrics.yml Ansible playbook. This is the playbook to use if you were deploying metrics for the first time on an existing cluster, but is also used to upgrade existing metrics deployments.

 If you have not already done so, see Specifying Metrics Ansible Variables in the Enabling Cluster Metrics topic and update your Ansible inventory file to at least set the following required variables within the [OSEv3:vars] section:

[OSEv3:vars]

openshift_metrics_install_metrics=true 1
openshift_metrics_image_version=<tag> 2
openshift_metrics_hawkular_hostname=<fqdn> 3
openshift_metrics_cassandra_storage_type=(emptydir|pv|dynamic) 4

- Enables the ability to upgrade the metrics deployment.
- Replace <tag> with v3.5 for the latest version.
- Used for the Hawkular Metrics route. Should correspond to a fully qualified domain name.
- Choose a type that is consistent with the previous deployment.
- 2. Add any other **openshift_metrics_*** variables that you want to specify to override the defaults, as described in Specifying Metrics Ansible Variables.
- When you have finished updating your inventory file, follow the instructions in Deploying the Metrics Deployment to run the openshift_metrics.yml playbook and complete the metrics deployment upgrade.

5.2.7. Verifying the Upgrade

To verify the upgrade:

1. If you are using a proxy, you must add the IP address of the etcd endpoints to the openshift_no_proxy cluster variable in your inventory file.

NOTE

If you are not using a proxy, you can skip this step.

In OpenShift Container Platform 3.4, the master connected to the etcd cluster using the host name of the etcd endpoints. In OpenShift Container Platform 3.5, the master now connects to etcd via IP address.

When configuring a cluster to use proxy settings (see Configuring Global Proxy Options), this change causes the master-to-etcd connection to be proxied as well, rather than being excluded by host name in each host's NO_PROXY setting (see Working with HTTP Proxies for more about NO_PROXY).

a. To workaround this issue, add the IP address of the etcd endpoint to the NO_PROXY environment variable on each master host's /etc/sysconfig/atomic-openshift-mastercontrollers file. For example:

```
NO_PROXY=https://<ip_address>:<port>
```

Use the IP that the master will use to contact the etcd cluster as the <ip_address>. The <port> should be 2379 if you are using standalone etcd (clustered) or 4001 for embedded etcd (single master, non-clustered etcd). The installer will be updated in a future release to handle this scenario automatically during installation and upgrades (BZ#1466783).

b. Restart the master service for the changes to take effect:

```
# systemctl restart atomic-openshift-master
```

2. Check that all nodes are marked as Ready:

```
# oc get nodes

NAME STATUS AGE

master.example.com Ready, SchedulingDisabled 165d
node1.example.com Ready 165d
node2.example.com Ready 165d
```

3. Then, verify that you are running the expected versions of the **docker-registry** and **router** images, if deployed. Replace < tag> with v3.5.5.31 for the latest version.

```
# oc get -n default dc/docker-registry -o json | grep \"image\"
    "image": "openshift3/ose-docker-registry:<tag>",
# oc get -n default dc/router -o json | grep \"image\"
    "image": "openshift3/ose-haproxy-router:<tag>",
```

4. You can use the diagnostics tool on the master to look for common issues:

```
# oc adm diagnostics
...
[Note] Summary of diagnostics execution:
[Note] Completed with no errors or warnings seen.
```

5.3. PERFORMING MANUAL IN-PLACE CLUSTER UPGRADES

5.3.1. Overview

IMPORTANT

An etcd performance issue has been discovered on new and upgraded OpenShift Container Platform 3.5 clusters. See the following Knowledgebase Solution for further details:

https://access.redhat.com/solutions/2916381 (BZ#1415839)

As an alternative to performing an automated upgrade, you can manually upgrade your OpenShift cluster. To manually upgrade without disruption, it is important to upgrade each component as documented in this topic.

Before you begin your upgrade, familiarize yourself now with the entire procedure. Specific releases may require additional steps to be performed at key points before or during the standard upgrade process.

IMPORTANT

Ensure that you have met all prerequisites before proceeding with an upgrade. Failure to do so can result in a failed upgrade.

5.3.2. Preparing for a Manual Upgrade

NOTE

Before upgrading your cluster to OpenShift Container Platform 3.5, the cluster must be already upgraded to the latest asynchronous release of version 3.4. Cluster upgrades cannot span more than one minor version at a time, so if your cluster is at a version earlier than 3.4, you must first upgrade incrementally (e.g., 3.2 to 3.3, then 3.3 to 3.4).

NOTE

Before attempting the upgrade, follow the steps in Verifying the Upgrade to verify the cluster's health. This will confirm that nodes are in the **Ready** state, running the expected starting version, and will ensure that there are no diagnostic errors or warnings.

To prepare for a manual upgrade, follow these steps:

IMPORTANT

If you have any **PetSet** objects in your cluster, see Migrating PetSets to StatefulSets before continuing.

1. If you are upgrading from OpenShift Container Platform 3.4 to 3.5, manually disable the 3.4 channel and enable the 3.5 channel on each host:

On RHEL 7 systems, also clear the yum cache:

```
# yum clean all
```

2. Install or update to the latest available version of the **atomic-openshift-utils** package on each RHEL 7 system, which provides files that will be used in later sections:

```
# yum install atomic-openshift-utils
```

3. Install or update to the following latest available *-excluder packages on each RHEL 7 system, which helps ensure your systems stay on the correct versions of atomic-openshift and docker packages when you are not trying to upgrade, according to the OpenShift Container Platform version:

```
# yum install atomic-openshift-excluder atomic-openshift-docker-
excluder
```

These packages add entries to the exclude directive in the host's /etc/yum.conf file.

4. Create an **etcd** backup on each master. The **etcd** package is required, even if using embedded etcd, for access to the **etcdctl** command to make the backup.

NOTE

The **etcd** package is installed by default for RHEL Atomic Host 7 systems. If the master is a RHEL 7 system and **etcd** is not already installed, install it now:

```
# yum install etcd
```

To create the backup, run:

```
# ETCD_DATA_DIR=/var/lib/origin/openshift.local.etcd 1
# etcdctl backup \
    --data-dir $ETCD_DATA_DIR \
    --backup-dir $ETCD_DATA_DIR.bak.<date> 2
```

- This directory is for embedded etcd. For external etcd, use /var/lib/etcd instead.
- Use the date of the backup, or some unique identifier, for <date>. The command will not make a backup if the --backup-dir location already exists.
- 5. For any upgrade path, ensure that you are running the latest kernel on each RHEL 7 system:

yum update kernel

5.3.3. Upgrading Master Components

Before upgrading any stand-alone nodes, upgrade the master components (which provide the *control plane* for the cluster).

1. Run the following command on each master to remove the **atomic-openshift** packages from the list of yum excludes on the host:

```
# atomic-openshift-excluder unexclude
```

- 2. Upgrade etcd on all master hosts and any external etcd hosts.
 - a. For RHEL 7 systems using the RPM-based method:
 - i. Upgrade the etcd package:

```
# yum update etcd
```

ii. Restart the **etcd** service and review the logs to ensure it restarts successfully:

```
# systemctl restart etcd
# journalctl -r -u etcd
```

- b. For RHEL Atomic Host 7 systems and RHEL 7 systems using the containerized method:
 - i. Pull the latest rhel7/etcd image:

```
# docker pull registry.access.redhat.com/rhel7/etcd
```

ii. Restart the etcd_container service and review the logs to ensure it restarts successfully:

```
# systemctl restart etcd_container
# journalctl -r -u etcd_container
```

- 3. On each master host, upgrade the atomic-openshift packages or related images.
 - a. For masters using the RPM-based method on a RHEL 7 system, upgrade all installed atomic-openshift packages and the openvswitch package:

```
# yum upgrade atomic-openshift\* openvswitch
```

- b. For masters using the containerized method on a RHEL 7 or RHEL Atomic Host 7 system, set the IMAGE_VERSION parameter to the version you are upgrading to in the following files:
 - /etc/sysconfig/atomic-openshift-master (single master clusters only)
 - /etc/sysconfig/atomic-openshift-master-controllers (multi-master clusters only)
 - /etc/sysconfig/atomic-openshift-master-api (multi-master clusters only)

- /etc/sysconfig/atomic-openshift-node
- /etc/sysconfig/atomic-openshift-openvswitch

For example:

```
IMAGE_VERSION=<tag>
```

Replace <tag> with v3.5.5.31 for the latest version.

4. Restart the master service(s) on each master and review logs to ensure they restart successfully.

For single master clusters:

```
# systemctl restart atomic-openshift-master
# journalctl -r -u atomic-openshift-master
```

For multi-master clusters:

```
# systemctl restart atomic-openshift-master-controllers
# systemctl restart atomic-openshift-master-api
# journalctl -r -u atomic-openshift-master-controllers
# journalctl -r -u atomic-openshift-master-api
```

5. Because masters also have node components running on them in order to be configured as part of the OpenShift SDN, restart the **atomic-openshift-node** and **openvswitch** services:

```
# systemctl restart openvswitch
# systemctl restart atomic-openshift-node
# journalctl -r -u openvswitch
# journalctl -r -u atomic-openshift-node
```

6. If you are performing a cluster upgrade that requires updating Docker to version 1.12, you must also perform the following steps if you are not already on Docker 1.12:

IMPORTANT

The node component on masters is set by default to unschedulable status during initial installation, so that pods are not deployed to them. However, it is possible to set them schedulable during the initial installation or manually thereafter. If any of your masters are also configured as a schedulable node, skip the following Docker upgrade steps for those masters and instead run all steps described in Upgrading Nodes when you get to that section for those hosts as well.

- a. Upgrade the docker package.
 - i. For RHEL 7 systems:

```
# yum update docker
```

Then, restart the docker service and review the logs to ensure it restarts successfully:

```
# systemctl restart docker
# journalctl -r -u docker
```

ii. For RHEL Atomic Host 7 systems, upgrade to the latest Atomic tree if one is available:

NOTE

If upgrading to RHEL Atomic Host 7.3.2, this upgrades Docker to version 1.12.

- # atomic host upgrade
- b. After the upgrade is completed and prepared for the next boot, reboot the host and ensure the **docker** service starts successfully:

```
# systemctl reboot
# journalctl -r -u docker
```

c. Remove the following file, which is no longer required:

```
# rm /etc/systemd/system/docker.service.d/docker-sdn-ovs.conf
```

7. Run the following command on each master to add the **atomic-openshift** packages back to the list of yum excludes on the host:

atomic-openshift-excluder exclude

NOTE

During the cluster upgrade, it can sometimes be useful to take a master out of rotation since some DNS client libraries will not properly to the other masters for cluster DNS. In addition to stopping the master and controller services, you can remove the EndPoint from the Kubernetes service's subsets.addresses.

\$ oc edit ep/kubernetes -n default

When the master is restarted, the Kubernetes service will be automatically updated.

5.3.4. Updating Policy Definitions

After a cluster upgrade, the recommended default cluster roles may be updated. To check if an update is recommended for your environment, you can run:

oadm policy reconcile-cluster-roles

WARNING

If you have customized default cluster roles and want to ensure a role reconciliation does not modify those customized roles, annotate them with **openshift.io/reconcile-protect** set to **true**. Doing so means you are responsible for manually updating those roles with any new or required permissions during upgrades.

This command outputs a list of roles that are out of date and their new proposed values. For example:

```
# oadm policy reconcile-cluster-roles
apiVersion: v1
items:
- apiVersion: v1
  kind: ClusterRole
  metadata:
     creationTimestamp: null
     name: admin
  rules:
     - attributeRestrictions: null
     resources:
     - builds/custom
...
```

NOTE

Your output will vary based on the OpenShift version and any local customizations you have made. Review the proposed policy carefully.

You can either modify this output to re-apply any local policy changes you have made, or you can automatically apply the new policy using the following process:

1. Reconcile the cluster roles:

```
# oadm policy reconcile-cluster-roles \
    --additive-only=true \
    --confirm
```

2. Reconcile the cluster role bindings:

Also run:

```
# oadm policy reconcile-cluster-role-bindings \
    system:build-strategy-jenkinspipeline \
    --confirm \
    -o name
```

3. Reconcile security context constraints:

```
# oadm policy reconcile-sccs \
    --additive-only=true \
    --confirm
```

5.3.5. Upgrading Nodes

After upgrading your masters, you can upgrade your nodes. When restarting the **atomic-openshift-node** service, there will be a brief disruption of outbound network connectivity from running pods to services while the **service proxy** is restarted. The length of this disruption should be very short and scales based on the number of services in the entire cluster.

NOTE

You can alternatively use the <u>blue-green deployment</u> method at this point to create a parallel environment for new nodes instead of upgrading them in place.

One at at time for each node that is not also a master, you must disable scheduling and evacuate its pods to other nodes, then upgrade packages and restart services.

1. Run the following command on each node to remove the **atomic-openshift** packages from the list of yum excludes on the host:

```
# atomic-openshift-excluder unexclude
```

2. As a user with cluster-admin privileges, disable scheduling for the node:

```
# oadm manage-node <node> --schedulable=false
```

3. Evacuate pods on the node to other nodes:

IMPORTANT

The --force option deletes any pods that are not backed by a replication controller.

```
# oadm drain <node> --force --delete-local-data --ignore-daemonsets
```

- 4. Upgrade the node component packages or related images.
 - a. For nodes using the RPM-based method on a RHEL 7 system, upgrade all installed atomicopenshift packages and the openvswitch package:

```
# yum upgrade atomic-openshift\* openvswitch
```

b. For nodes using the containerized method on a RHEL 7 or RHEL Atomic Host 7 system, set the IMAGE_VERSION parameter in the /etc/sysconfig/atomic-openshift-node and /etc/sysconfig/openvswitch files to the version you are upgrading to. For example:

```
IMAGE_VERSION=<tag>
```

Replace <tag> with v3.5.5.31 for the latest version.

5. Restart the **atomic-openshift-node** and **openvswitch** services and review the logs to ensure they restart successfully:

```
# systemctl restart openvswitch
# systemctl restart atomic-openshift-node
# journalctl -r -u atomic-openshift-node
# journalctl -r -u openvswitch
```

- 6. If you are performing a cluster upgrade that requires updating Docker to version 1.12, you must also perform the following steps if you are not already on Docker 1.12:
 - a. Upgrade the docker package.
 - i. For RHEL 7 systems:

```
# yum update docker
```

Then, restart the **docker** service and review the logs to ensure it restarts successfully:

```
# systemctl restart docker
# journalctl -r -u docker
```

After Docker is restarted, restart the **atomic-openshift-node** service again and review the logs to ensure it restarts successfully:

```
# systemctl restart atomic-openshift-node
# journalctl -r -u atomic-openshift-node
```

ii. For RHEL Atomic Host 7 systems, upgrade to the latest Atomic tree if one is available:

NOTE

If upgrading to RHEL Atomic Host 7.3.2, this upgrades Docker to version 1.12.

```
# atomic host upgrade
```

After the upgrade is completed and prepared for the next boot, reboot the host and ensure the **docker** service starts successfully:

```
# systemctl reboot
# journalctl -r -u docker
```

b. Remove the following file, which is no longer required:

rm /etc/systemd/system/docker.service.d/docker-sdn-ovs.conf

7. Re-enable scheduling for the node:

```
# oadm manage-node <node> --schedulable
```

8. Run the following command on each node to add the **atomic-openshift** packages back to the list of yum excludes on the host:

```
# atomic-openshift-excluder exclude
```

- 9. Repeat the previous steps on the next node, and continue repeating these steps until all nodes have been upgraded.
- 10. After all nodes have been upgraded, as a user with **cluster-admin** privileges, verify that all nodes are showing as **Ready**:

```
# oc get nodes

NAME STATUS AGE

master.example.com Ready, SchedulingDisabled 165d
node1.example.com Ready 165d
node2.example.com Ready 165d
```

5.3.6. Upgrading the Router

If you have previously deployed a router, the router deployment configuration must be upgraded to apply updates contained in the router image. To upgrade your router without disrupting services, you must have previously deployed a highly-available routing service.

Edit your router's deployment configuration. For example, if it has the default router name:

```
# oc edit dc/router
```

Apply the following changes:

```
spec:
  template:
    spec:
    containers:
    - env:
        ...
        image: registry.access.redhat.com/openshift3/ose-haproxy-router:
<tag>
    imagePullPolicy: IfNotPresent
        ...
```

Adjust <tag> to match the version you are upgrading to (use v3.5.5.31 for the latest version).

You should see one router pod updated and then the next.

5.3.7. Upgrading the Registry

The registry must also be upgraded for changes to take effect in the registry image. If you have used a **PersistentVolumeClaim** or a host mount point, you may restart the registry without losing the contents of your registry. Storage for the Registry details how to configure persistent storage for the registry.

Edit your registry's deployment configuration:

```
# oc edit dc/docker-registry
```

Apply the following changes:

```
spec:
  template:
    spec:
    containers:
    - env:
        ...
        image: registry.access.redhat.com/openshift3/ose-docker-registry:
<tag> 1
        imagePullPolicy: IfNotPresent
        ...
```

Adjust <tag> to match the version you are upgrading to (use v3.5.5.31 for the latest version).

IMPORTANT

Images that are being pushed or pulled from the internal registry at the time of upgrade will fail and should be restarted automatically. This will not disrupt pods that are already running.

5.3.8. Updating the Default Image Streams and Templates

By default, the quick and advanced installation methods automatically create default image streams, InstantApp templates, and database service templates in the openshift project, which is a default project to which all users have view access. These objects were created during installation from the JSON files located under the /usr/share/ansible/openshift-ansible/roles/openshift_examples/files/examples/directory.

NOTE

Because RHEL Atomic Host 7 cannot use **yum** to update packages, the following steps must take place on a RHEL 7 system.

 Update the packages that provide the example JSON files. On a subscribed Red Hat Enterprise Linux 7 system where you can run the CLI as a user with cluster-admin permissions, install or update to the latest version of the atomic-openshift-utils package, which should also update the openshift-ansible- packages:

```
# yum update atomic-openshift-utils
```

The openshift-ansible-roles package provides the latest example JSON files.

2. After a manual upgrade, get the latest templates from openshift-ansible-roles:

```
rpm -ql openshift-ansible-roles | grep examples | grep v1.5
```

In this example, /usr/share/ansible/openshiftansible/roles/openshift_examples/files/examples/v1.5/image-streams/image-streamsrhel7.json is the latest file that you want in the latest openshift-ansible-roles package.

/usr/share/openshift/examples/image-streams/image-streams-rhel7.json is not owned by a package, but is updated by Ansible. If you are upgrading outside of Ansible. you need to get the latest .json files on the system where you are running oc, which can run anywhere that has access to the master.

3. Install atomic-openshift-utils and its dependencies to install the new content into /usr/share/ansible/openshift-ansible/roles/openshift_examples/files/examples/v1.5/::

```
$ oc create -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/image-
streams/image-streams-rhel7.json
$ oc create -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/image-
streams/dotnet_imagestreams.json
$ oc replace -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/image-
streams/image-streams-rhel7.json
$ oc replace -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/image-
streams/dotnet_imagestreams.json
```

4. Update the templates:

```
$ oc create -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/quickstart-
templates/
$ oc create -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/db-templates/
$ oc create -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/infrastructure-
templates/
$ oc create -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/xpaas-
templates/
$ oc create -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/xpaas-streams/
$ oc replace -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/quickstart-
templates/
$ oc replace -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/db-templates/
$ oc replace -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/infrastructure-
templates/
$ oc replace -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/xpaas-
```

```
templates/
$ oc replace -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/xpaas-streams/
```

Errors are generated for items that already exist. This is expected behavior:

```
# oc create -n openshift -f /usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/quickstart-
templates/
Error from server: error when creating
"/usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/quickstart-
templates/cakephp-mysql.json": templates "cakephp-mysql-example"
already exists
Error from server: error when creating
"/usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/quickstart-
templates/cakephp.json": templates "cakephp-example" already exists
Error from server: error when creating
"/usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/quickstart-
templates/dancer-mysql.json": templates "dancer-mysql-example"
already exists
Error from server: error when creating
"/usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/quickstart-
templates/dancer.json": templates "dancer-example" already exists
Error from server: error when creating
"/usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/quickstart-
templates/django-postgresql.json": templates "django-psql-example"
already exists
```

Now, content can be updated. Without running the automated upgrade playbooks, the content is not updated in /usr/share/openshift/.

5.3.9. Importing the Latest Images

After updating the default image streams, you may also want to ensure that the images within those streams are updated. For each image stream in the default **openshift** project, you can run:

```
# oc import-image -n openshift <imagestream>
```

For example, get the list of all image streams in the default **openshift** project:

```
nodejs registry.access.redhat.com/openshift3/nodejs-010-rhel7
0.10,latest,v3.1.1.6 16 hours ago
...
```

Update each image stream one at a time:

```
# oc import-image -n openshift nodejs
The import completed successfully.
```

IMPORTANT

In order to update your S2I-based applications, you must manually trigger a new build of those applications after importing the new images using oc start-build <app-name>.

5.3.10. Upgrading the EFK Logging Stack

NOTE

Manual upgrade steps for logging deployments are no longer available starting in OpenShift Container Platform 3.5.

To upgrade an existing EFK logging stack deployment, you must use the provided /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-cluster/openshift-logging.yml Ansible playbook. This is the playbook to use if you were deploying logging for the first time on an existing cluster, but is also used to upgrade existing logging deployments.

 If you have not already done so, see Specifying Logging Ansible Variables in the Aggregating Container Logs topic and update your Ansible inventory file to at least set the following required variable within the [OSEv3:vars] section:

[OSEv3:vars]

openshift_logging_install_logging=true 1
openshift_logging_image_version=<tag> 2

- Enables the ability to upgrade the logging stack.
- Replace <tag> with v3.5 for the latest version.
- 2. Add any other **openshift_logging_*** variables that you want to specify to override the defaults, as described in Specifying Logging Ansible Variables.
- 3. When you have finished updating your inventory file, follow the instructions in Deploying the EFK Stack to run the *openshift-logging.yml* playbook and complete the logging deployment upgrade.

5.3.11. Upgrading Cluster Metrics

NOTE

Manual upgrade steps for metrics deployments are no longer available starting in OpenShift Container Platform 3.5.

To upgrade an existing cluster metrics deployment, you must use the provided /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-cluster/openshift-metrics.yml Ansible playbook. This is the playbook to use if you were deploying metrics for the first time on an existing cluster, but is also used to upgrade existing metrics deployments.

 If you have not already done so, see Specifying Metrics Ansible Variables in the Enabling Cluster Metrics topic and update your Ansible inventory file to at least set the following required variables within the [OSEv3:vars] section:

[OSEv3:vars]

```
openshift_metrics_install_metrics=true 1
openshift_metrics_image_version=<tag> 2
openshift_metrics_hawkular_hostname=<fqdn> 3
openshift_metrics_cassandra_storage_type=(emptydir|pv|dynamic) 4
```

- Enables the ability to upgrade the metrics deployment.
- Replace < tag> with v3.5 for the latest version.
- Used for the Hawkular Metrics route. Should correspond to a fully qualified domain name.
- Choose a type that is consistent with the previous deployment.
- 2. Add any other **openshift_metrics_*** variables that you want to specify to override the defaults, as described in Specifying Metrics Ansible Variables.
- 3. When you have finished updating your inventory file, follow the instructions in Deploying the Metrics Deployment to run the *openshift_metrics.yml* playbook and complete the metrics deployment upgrade.

5.3.12. Additional Manual Steps Per Release

Some OpenShift Container Platform releases may have additional instructions specific to that release that must be performed to fully apply the updates across the cluster. This section will be updated over time as new asynchronous updates are released for OpenShift Container Platform 3.5.

See the OpenShift Container Platform 3.5 Release Notes to review the latest release notes.

5.3.12.1. OpenShift Container Platform 3.5.5.5

Migrating PetSets to StatefulSets

PetSet obects are an Alpha feature in upstream Kubernetes 1.4 and are not supported by Red Hat. In Kubernetes 1.5, they are replaced by the Beta feature **StatefulSets**. Red Hat currently does not offer support for either PetSets or StatefulSets.

If you have any existing **PetSets** in your cluster, they MUST be removed before upgrading to OpenShift Container Platform 3.5. Automatically migrating **PetSets** to **StatefulSets** in OpenShift Container Platform 3.5 is not supported. See the Kubernetes "Upgrading from PetSets to StatefulSets" documentation for additional information:

https://kubernetes.io/docs/tasks/manage-stateful-set/upgrade-pet-set-to-stateful-set/

Red Hat strongly recommends reading the above referenced documentation in its entirety before taking any destructive actions.

If you want to simply remove all **PetSets** without manually migrating to **StatefulSets**, run this command as a user with **cluster-admin** privileges:

\$ oc get petsets --all-namespaces -o yaml | oc delete -f - --cascade=false

Migrating Jobs

With deprecation of the extensions/v1beta1. Job resource, you must migrate all Job resources to use the batch/v1. Job instead. To verify which objects will be migrated, run:

\$ oadm migrate storage --include=jobs

You can also increase the log level using the **--loglevel** flag. When you are ready to perform the actual migration, add the **--confirm** option:

\$ oadm migrate storage --include=jobs --confirm

5.3.12.2. OpenShift Container Platform 3.5.5.8

There are no additional manual steps for the upgrade to OpenShift Container Platform 3.5.5.8 that are not already mentioned inline during the standard manual upgrade process.

5.3.12.3. OpenShift Container Platform 3.5.5.24

There are no additional manual steps for the upgrade to OpenShift Container Platform 3.5.5.24 that are not already mentioned inline during the standard manual upgrade process.

5.3.12.4. OpenShift Container Platform 3.5.5.26

There are no additional manual steps for the upgrade to OpenShift Container Platform 3.5.5.26 that are not already mentioned inline during the standard manual upgrade process.

5.3.12.5. OpenShift Container Platform 3.5.5.31

There are no additional manual steps for the upgrade to OpenShift Container Platform 3.5.5.31 that are not already mentioned inline during the standard manual upgrade process.

5.3.13. Verifying the Upgrade

To verify the upgrade:

1. If you are using a proxy, you must add the IP address of the etcd endpoints to the openshift_no_proxy cluster variable in your inventory file.

NOTE

If you are not using a proxy, you can skip this step.

In OpenShift Container Platform 3.4, the master connected to the etcd cluster using the host name of the etcd endpoints. In OpenShift Container Platform 3.5, the master now connects to etcd via IP address.

When configuring a cluster to use proxy settings (see Configuring Global Proxy Options), this change causes the master-to-etcd connection to be proxied as well, rather than being excluded by host name in each host's NO_PROXY setting (see Working with HTTP Proxies for more about NO_PROXY).

a. To workaround this issue, add the IP address of the etcd endpoint to the NO_PROXY environment variable on each master host's /etc/sysconfig/atomic-openshift-mastercontrollers file. For example:

```
NO_PROXY=https://<ip_address>:<port>
```

Use the IP that the master will use to contact the etcd cluster as the <ip_address>. The <port> should be 2379 if you are using standalone etcd (clustered) or 4001 for embedded etcd (single master, non-clustered etcd). The installer will be updated in a future release to handle this scenario automatically during installation and upgrades (BZ#1466783).

b. Restart the master service for the changes to take effect:

```
# systemctl restart atomic-openshift-master
```

2. Check that all nodes are marked as Ready:

```
# oc get nodes

NAME STATUS AGE

master.example.com Ready, SchedulingDisabled 165d

node1.example.com Ready 165d

node2.example.com Ready 165d
```

3. Verify that you are running the expected versions of the **docker-registry** and **router** images, if deployed. Replace <tag> with v3.5.5.31 for the latest version.

```
# oc get -n default dc/docker-registry -o json | grep \"image\"
    "image": "openshift3/ose-docker-registry:<tag>",
```

```
# oc get -n default dc/router -o json | grep \"image\"
    "image": "openshift3/ose-haproxy-router:<tag>",
```

4. Use the diagnostics tool on the master to look for common issues:

```
# oadm diagnostics
...
[Note] Summary of diagnostics execution:
[Note] Completed with no errors or warnings seen.
```

5.4. BLUE-GREEN DEPLOYMENTS

5.4.1. Overview

IMPORTANT

An etcd performance issue has been discovered on new and upgraded OpenShift Container Platform 3.5 clusters. See the following Knowledgebase Solution for further details:

https://access.redhat.com/solutions/2916381 (BZ#1415839)

NOTE

This topic serves as an alternative approach for node host upgrades to the in-place upgrade method.

The blue-green deployment upgrade method follows a similar flow to the in-place method: masters and etcd servers are still upgraded first, however a parallel environment is created for new node hosts instead of upgrading them in-place.

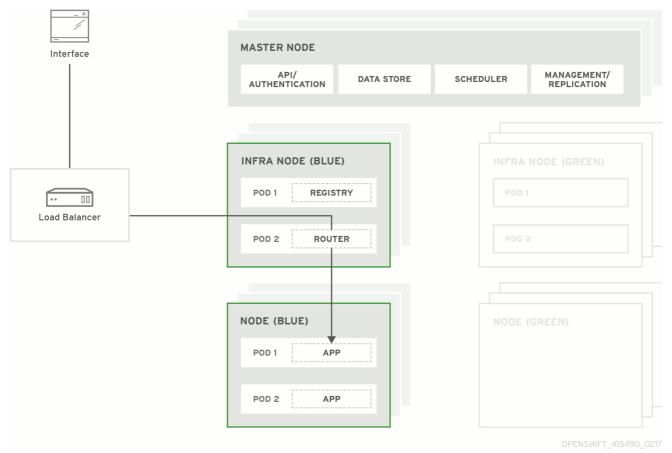

This method allows administrators to switch traffic from the old set of node hosts (e.g., the *blue* deployment) to the new set (e.g., the *green* deployment) after the new deployment has been verified. If a problem is detected, it is also then easy to rollback to the old deployment quickly.

While blue-green is a proven and valid strategy for deploying just about any software, there are always trade-offs. Not all environments have the same uptime requirements or the resources to properly perform blue-green deployments.

In an OpenShift Container Platform environment, the most suitable candidate for blue-green deployments are the node hosts. All user processes run on these systems and even critical pieces of OpenShift Container Platform infrastructure are self-hosted on these resources. Uptime is most important for these workloads and the additional complexity of blue-green deployments can be justified.

The exact implementation of this approach varies based on your requirements. Often the main challenge is having the excess capacity to facilitate such an approach.

Figure 5.1. Blue-Green Deployment

5.4.2. Preparing for a Blue-Green Upgrade

After you have upgraded your master and etcd hosts using method described for In-place Upgrades, use the following sections to prepare your environment for a blue-green upgrade of the remaining node hosts.

5.4.2.1. Sharing Software Entitlements

Administrators must temporarily share the Red Hat software entitlements between the blue-green deployments or provide access to the installation content by means of a system such as Red Hat Satellite. This can be accomplished by sharing the consumer ID from the previous node host:

1. On each old node host that will be upgraded, note its **system identity** value, which is the consumer ID:

```
# subscription-manager identity | grep system
system identity: 6699375b-06db-48c4-941e-689efd6ce3aa
```

2. On each new RHEL 7 or RHEL Atomic Host 7 system that is going to replace an old node host, register using the respective consumer ID from the previous step:

```
# subscription-manager register --consumerid=6699375b-06db-48c4-941e-689efd6ce3aa
```

IMPORTANT

After a successful deployment, remember to unregister the old host with subscription-manager clean to prevent the environment from being out of compliance.

5.4.2.2. Labeling Blue Nodes

You must ensure that your current node hosts in production are labeled either **blue** or **green**. In this example, the current production environment will be **blue** and the new environment will be **green**.

1. Get the current list of node names known to the cluster:

```
$ oc get nodes
```

Ensure that all hosts have appropriate node labels. Consider that by default, all master hosts
are also configured as unschedulable node hosts (so that they are joined to the pod network).
Additional labels will assist in management of clusters, specifically labeling hosts as their
types (e.g., type=master or type=node) should assist management.

For example, to label node hosts that are also masters as **type=master**, run the following for each relevant <node_name>:

```
$ oc label node <node_name> type=master
```

To label non-master node hosts as type=node, run the following for each relevant <node_name>:

```
$ oc label node <node_name> type=node
```

Alternatively, if you have already finished labeling certain nodes with type=master and just want to label all remaining nodes as type=node, you can use the --all option and any hosts that already had a type= set will not be overwritten:

```
$ oc label node --all type=node
```

3. Label all non-master node hosts in your current production environment to **color=blue**. For example, using the labels described in the previous step:

```
$ oc label node -1 type=node color=blue
```

In the above command, the -1 flag is used to match a subset of the environment using the selector type=node, and all matches are labeled with color=blue.

5.4.2.3. Creating and Labeling Green Nodes

Create the new green environment for any node hosts that are to be replaced by adding an equal number of new node hosts to the existing cluster. You can use either the quick installer or advanced install method as described in Adding Hosts to an Existing Cluster.

When adding these new nodes, use the following Ansible variables:

- Apply the color=green label automatically during the installation of these hosts by setting
 the openshift_node_labels variable for each node host. You can always adjust the labels
 after installation as well, if needed, using the oc label node command.
- In order to delay workload scheduling until the nodes are deemed healthy (which you will verify
 in later steps), set the openshift_schedulable=false variable for each node host to
 ensure they are unschedulable initially.

Example new_nodes Host Group

Add the following to your existing inventory. Everything that was in your inventory previously should remain.

```
[new_nodes]
node4.example.com openshift_node_labels="{'region': 'primary',
  'color':'green'}" openshift_schedulable=false
node5.example.com openshift_node_labels="{'region': 'primary',
  'color':'green'}" openshift_schedulable=false
node6.example.com openshift_node_labels="{'region': 'primary',
  'color':'green'}" openshift_schedulable=false
infra-node3.example.com openshift_node_labels="{'region': 'infra',
  'color':'green'}" openshift_schedulable=false
infra-node4.example.com openshift_node_labels="{'region': 'infra',
  'color':'green'}" openshift_schedulable=false
```

5.4.2.4. Verifying Green Nodes

Verify that your new green nodes are in a healthy state. Perform the following checklist:

1. Verify that new nodes are detected in the cluster and are in **Ready** state:

```
$ oc get nodes
ip-172-31-49-10.ec2.internal Ready 3d
```

2. Verify that the green nodes have proper labels:

```
$ oc get nodes -o wide --show-labels

ip-172-31-49-10.ec2.internal Ready 4d
beta.kubernetes.io/arch=amd64, beta.kubernetes.io/instance-
type=m4.large, beta.kubernetes.io/os=linux, color=green, failure-
domain.beta.kubernetes.io/region=us-east-1, failure-
domain.beta.kubernetes.io/zone=us-east-1c, hostname=openshift-
cluster-1d005, kubernetes.io/hostname=ip-172-31-49-
10.ec2.internal, region=us-east-1, type=infra
```

3. Perform a diagnostic check for the cluster:

```
$ oadm diagnostics
[Note] Determining if client configuration exists for client/cluster
diagnostics
Info: Successfully read a client config file at
'/root/.kube/config'
```

Info: Using context for cluster-admin access: 'default/internalapi-upgradetest-openshift-com:443/system:admin' [Note] Performing systemd discovery

[Note] Running diagnostic: ConfigContexts[default/api-upgradetest-openshift-com:443/system:admin]

 $\label{eq:decomposition} \textbf{Description: Validate client config context is complete and has connectivity}$

. . .

[Note] Running diagnostic: CheckExternalNetwork

Description: Check that external network is accessible within a pod

[Note] Running diagnostic: CheckNodeNetwork

Description: Check that pods in the cluster can access its own node.

[Note] Running diagnostic: CheckPodNetwork
Description: Check pod to pod communication in the cluster. In case of ovs-subnet network plugin, all pods should be able to communicate with each other and in case of multitenant network plugin, pods in non-global projects should be isolated and pods in global projects should be able to access any pod in the cluster and vice versa.

[Note] Running diagnostic: CheckServiceNetwork

Description: Check pod to service communication in the cluster. In case of ovs-subnet network plugin, all pods should be able to communicate with all services and in case of multitenant network plugin, services in non-global projects should be isolated and pods in global projects should be able to access any service in the cluster.
...

5.4.3. Registry and Router Canary Deployments

A common practice is to scale the registry and router pods until they are migrated to new (green) infrastructure node hosts. For these pods, a *canary* deployment approach is commonly used.

Scaling these pods up will make them immediately active on the new infrastructure nodes. Pointing their deployment configuration to the new image initiates a rolling update. However, because of node anti-affinity, and the fact that the blue nodes are still unschedulable, the deployments to the old nodes will fail.

At this point, the registry and router deployments can be scaled down to the original number of pods. At any given point, the original number of pods is still available so no capacity is lost and downtime should be avoided.

5.4.4. Warming the Green Nodes

In order for pods to be migrated from the blue environment to the green, the required container images must be pulled. Network latency and load on the registry can cause delays if there is not sufficient capacity built in to the environment.

Often, the best way to minimize impact to the running system is to trigger new pod deployments that will land on the new nodes. Accomplish this by importing new image streams.

Major releases of OpenShift Container Platform (and sometimes asynchronous errata updates) introduce new image streams for builder images for users of Source-to-Image (S2I). Upon import, any builds or deployments configured with image change triggers are automatically created.

Another benefit of triggering the builds is that it does a fairly good job of fetching the majority of the ancillary images to all node hosts such as the various builder images, the pod infrastructure image, and deployers. Everything else can be moved over using node evacuation in a later step and will proceed more quickly as a result.

When you are ready to continue with the upgrade process, follow these steps to warm the green nodes:

- 1. Disable the blue nodes so that no new pods are run on them by setting them unschedulable:
 - \$ oadm manage-node --schedulable=false --selector=color=blue
- 2. Set the green nodes to schedulable so that new pods only land on them:
 - \$ oadm manage-node --schedulable=true --selector=color=green
- 3. Update the default image streams and templates as described in Manual In-place Upgrades.
- 4. Import the latest images as described in Manual In-place Upgrades.
 It is important to realize that this process can trigger a large number of builds. The good news is that the builds are performed on the green nodes and, therefore, do not impact any traffic on the blue deployment.
- 5. To monitor build progress across all namespaces (projects) in the cluster:

```
$ oc get events -w --all-namespaces
```

In large environments, builds rarely completely stop. However, you should see a large increase and decrease caused by the administrative image import.

5.4.5. Evacuating and Decommissioning Blue Nodes

For larger deployments, it is possible to have other labels that help determine how evacuation can be coordinated. The most conservative approach for avoiding downtime is to evacuate one node host at a time.

If services are composed of pods using zone anti-affinity, then an entire zone can be evacuated at once. It is important to ensure that the storage volumes used are available in the new zone as this detail can vary among cloud providers.

In OpenShift Container Platform 3.2 and later, a node host evacuation is triggered whenever the node service is stopped. Node labeling is very important and can cause issues if nodes are mislabled or commands are run on nodes with generalized labels. Exercise caution if master hosts are also labeled with color=blue.

When you are ready to continue with the upgrade process, follow these steps.

- 1. Evacuate and delete all blue nodes by following one of the following options:
 - a. Option A Manually evacuate then delete the color=blue nodes with the following

commands:

```
$ oadm manage-node --selector=color=blue --evacuate
$ oc delete node --selector=color=blue
```

- b. **Option B** Filter out the masters before running the **delete** command:
 - i. Verify the list of blue node hosts are as expected by running:

```
$ oc get nodes -o go-template='{{ range .items }}{{ if and (eq
.metadata.labels.foo "bar") \
        (ne .metadata.labels.type "master") }}{{ .metadata.name }}
{{ "\n" }}{{end}}{{ end }}';
```

ii. After the list is determined to be of the blue nodes, run:

```
$ for i in $(oc get nodes -o \
    go-template='{{ range .items }}{{ if and (eq
.metadata.labels.color "blue") \
        (ne .metadata.labels.type "master") }}{{ .metadata.name }}
{{ "\n" }}{{end}}{{ end }}'); \
    do
        oc delete node $i
done
```

- 2. After the blue node hosts no longer contain pods and have been removed from OpenShift Container Platform they are safe to power off. As a safety precaution, leaving the hosts around for a short period of time can prove beneficial if the upgrade has issues.
- 3. Ensure that any desired scripts or files are captured before terminating these hosts. After a determined time period and capacity is not an issue, remove these hosts.

5.5. OPERATING SYSTEM UPDATES AND UPGRADES

5.5.1. Updating and Upgrading the Operating System

Updating or upgrading your operating system (OS), by either changing OS versions or updating the system software, can impact the OpenShift Container Platform software running on those machines. In particular, these updates can affect the **iptables** rules or **ovs** flows that OpenShift Container Platform requires to operate.

Use the following to safely upgrade the OS on a host:

1. Ensure the host is unschedulable, meaning that no new pods will be placed onto the host:

```
$ oadm manage-node <node_name> --schedulable=false
```

2. Migrate the pods from the host:

```
$ oadm drain <node_name> --force --delete-local-data --ignore-
daemonsets
```

3. Install or update the *-excluder packages on each host with the following. This ensures the hosts stay on the correct versions of OpenShift Container Platform, as per the atomic-openshift and docker packages, instead of the most current versions:

yum install atomic-openshift-excluder atomic-openshift-dockerexcluder

This adds entries to the exclude directive in the host's /etc/yum.conf file.

- 4. Update or upgrade the host packages, and reboot the host. A reboot ensures that the host is running the newest versions, and means that the docker and OpenShift Container Platform processes have been restarted, which will force them to check that all of the rules in other services are correct.
 - However, instead of rebooting a node host, you can restart the services that are affected, or preserve the **iptables** state. Both processes are described in the OpenShift Container Platform IPtables topic. The ovs flow rules do not need to be saved, but restarting the OpenShift Container Platform node software will fix the flow rules.
- 5. Configure the host to be schedulable again:
 - \$ oadm manage-node <node_name> --schedulable=true

CHAPTER 6. DOWNGRADING OPENSHIFT

6.1. OVERVIEW

Following an OpenShift Container Platform upgrade, it may be desirable in extreme cases to downgrade your cluster to a previous version. The following sections outline the required steps for each system in a cluster to perform such a downgrade for the OpenShift Container Platform 3.5 to 3.4 downgrade path.

WARNING

These steps are currently only supported for RPM-based installations of OpenShift Container Platform and assumes downtime of the entire cluster.

6.2. VERIFYING BACKUPS

The Ansible playbook used during the upgrade process should have created a backup of the master-config.yaml file and the etcd data directory. Ensure these exist on your masters and etcd members:

/etc/origin/master/master-config.yaml.<timestamp>
/var/lib/origin/etcd-backup-<timestamp>

Also, back up the *node-config.yaml* file on each node (including masters, which have the node component on them) with a timestamp:

/etc/origin/node/node-config.yaml.<timestamp>

If you are using an external etcd cluster (versus the single embedded etcd), the backup is likely created on all etcd members, though only one is required for the recovery process.

The RPM downgrade process in a later step should create *.rpmsave* backups of the following files, but it may be a good idea to keep a separate copy regardless:

/etc/sysconfig/atomic-openshift-master
/etc/etcd/etcd.conf 1

Only required if using external etcd.

6.3. SHUTTING DOWN THE CLUSTER

On all masters, nodes, and etcd members (if using an external etcd cluster), ensure the relevant services are stopped.

On the master in a single master cluster:

systemctl stop atomic-openshift-master

On each master in a multi-master cluster:

```
# systemctl stop atomic-openshift-master-api
# systemctl stop atomic-openshift-master-controllers
```

On all master and node hosts:

```
# systemctl stop atomic-openshift-node
```

On any external etcd hosts:

```
# systemctl stop etcd
```

6.4. REMOVING RPMS

 The *-excluder packages add entries to the exclude directive in the host's /etc/yum.conf file when installed. Run the following command on each host to remove the atomic-openshift-* and docker packages from the exclude list:

```
# atomic-openshift-excluder unexclude
# atomic-openshift-docker-excluder unexclude
```

2. On all masters, nodes, and etcd members (if using an external etcd cluster), remove the following packages:

```
# yum remove atomic-openshift \
   atomic-openshift-clients \
   atomic-openshift-node \
   atomic-openshift-master \
   openvswitch \
   atomic-openshift-sdn-ovs \
   tuned-profiles-atomic-openshift-node\
   atomic-openshift-excluder\
   atomic-openshift-docker-excluder
```

3. If you are using external etcd, also remove the etcd package:

```
# yum remove etcd
```

If using the embedded etcd, leave the **etcd** package installed. It is required for running the **etcdctl** command to issue operations in later steps.

6.5. DOWNGRADING DOCKER

Both OpenShift Container Platform 3.4 and 3.5 require Docker 1.12, so Docker does not need to be downgraded.

6.6. REINSTALLING RPMS

Disable the OpenShift Container Platform 3.5 repositories, and re-enable the 3.4 repositories:

```
# subscription-manager repos \
    --disable=rhel-7-server-ose-3.5-rpms \
    --enable=rhel-7-server-ose-3.4-rpms
```

On each master, install the following packages:

```
# yum install atomic-openshift \
   atomic-openshift-clients \
   atomic-openshift-node \
   atomic-openshift-master \
   openvswitch \
   atomic-openshift-sdn-ovs \
   tuned-profiles-atomic-openshift-node \
   atomic-openshift-excluder \
   atomic-openshift-docker-excluder
```

On each node, install the following packages:

```
# yum install atomic-openshift \
   atomic-openshift-node \
   openvswitch \
   atomic-openshift-sdn-ovs \
   tuned-profiles-atomic-openshift-node \
   atomic-openshift-excluder \
   atomic-openshift-docker-excluder
```

If using an external etcd cluster, install the following package on each etcd member:

```
# yum install etcd
```

6.7. RESTORING ETCD

See Backup and Restore.

6.8. BRINGING OPENSHIFT CONTAINER PLATFORM SERVICES BACK ONLINE

See Backup and Restore.

6.9. VERIFYING THE DOWNGRADE

1. To verify the downgrade, first check that all nodes are marked as **Ready**:

```
# oc get nodes

NAME STATUS AGE

master.example.com Ready, SchedulingDisabled 165d
node1.example.com Ready 165d
node2.example.com Ready 165d
```

2. Then, verify that you are running the expected versions of the **docker-registry** and **router** images, if deployed:

```
# oc get -n default dc/docker-registry -o json | grep \"image\"
    "image": "openshift3/ose-docker-registry:v3.4.1.37-2",
# oc get -n default dc/router -o json | grep \"image\"
    "image": "openshift3/ose-haproxy-router:v3.4.1.37-2",
```

3. You can use the diagnostics tool on the master to look for common issues and provide suggestions:

```
# oc adm diagnostics
...
[Note] Summary of diagnostics execution:
[Note] Completed with no errors or warnings seen.
```

CHAPTER 7. MASTER AND NODE CONFIGURATION

7.1. OVERVIEW

The openshift start command is used to launch OpenShift Container Platform servers. The command and its subcommands (master to launch a master server and node to launch a node server) all take a limited set of arguments that are sufficient for launching servers in a development or experimental environment.

However, these arguments are insufficient to describe and control the full set of configuration and security options that are necessary in a production environment. To provide those options, it is necessary to use the dedicated master and node configuration files.

Master configuration files and node configuration files are fully specified with no default values. Therefore, any empty value indicates that you want to start up with an empty value for that parameter. This makes it easy to reason about exactly what your configuration is, but it also makes it difficult to remember all of the options to specify. To make this easier, the configuration files can be created with the --write-config option and then used with the --config option.

7.2. MASTER CONFIGURATION FILES

This section reviews parameters mentioned in the *master-config.yaml* file.

You can create a new master configuration file to see the valid options for your installed version of OpenShift Container Platform.

IMPORTANT

Whenever you modify the *master-config.yaml* file, you must restart the master for the changes to take effect.

7.2.1. Admission Control Configuration

Table 7.1. Admission Control Configuration Parameters

Parameter Name	Description
AdmissionConfig	Contains admission control plug-in configuration.
APIServerArguments	Key-value pairs that will be passed directly to the Kube API server that match the API servers' command line arguments. These are not migrated, but if you reference a value that does not exist the server will not start. These values may override other settings in KubernetesMasterConfig, which may cause invalid configurations.
ControllerArguments	Key-value pairs that will be passed directly to the Kube controller manager that match the controller manager's command line arguments. These are not migrated, but if you reference a value that does not exist the server will not start. These values may override other settings in KubernetesMasterConfig , which may cause invalid configurations.

Parameter Name	Description
DefaultAdmissionConfig	Used to enable or disable various admission plug-ins. When this type is present as the configuration object under pluginConfig and if the admission plug-in supports it, this will cause an off by default admission plug-in to be enabled.
PluginConfig	Allows specifying a configuration file per admission control plug-in.
PluginOrderOverride	A list of admission control plug-in names that will be installed on the master. Order is significant. If empty, a default list of plug-ins is used.
SchedulerArguments	Key-value pairs that will be passed directly to the Kube scheduler that match the scheduler's command line arguments. These are not migrated, but if you reference a value that does not exist the server will not start. These values may override other settings in <pre>KubernetesMasterConfig</pre> , which may cause invalid configurations.

7.2.2. Asset Configuration

Table 7.2. Asset Configuration Parameters

Parameter Name	Description
AssetConfig	Holds the necessary configuration options for serving assets.
DisabledFeatures	A list of features that should not be started. You will likely want to set this as null . It is very unlikely that anyone will want to manually disable features and that is not encouraged.
Extensions	Files to serve from the asset server file system under a subcontext.
ExtensionDevelopment	When set to true , tells the asset server to reload extension scripts and stylesheets for every request rather than only at startup. It lets you develop extensions without having to restart the server for every change.
ExtensionProperties	Key- (string) and value- (string) pairs that will be injected into the console under the global variable OPENSHIFT_EXTENSION_PROPERTIES.
ExtensionScripts	File paths on the asset server files to load as scripts when the web console loads.
ExtensionStylesheets	File paths on the asset server files to load as style sheets when the web console loads.
LoggingPublicURL	The public endpoint for logging (optional).

Parameter Name	Description
LogoutURL	An optional, absolute URL to redirect web browsers to after logging out of the web console. If not specified, the built-in logout page is shown.
MasterPublicURL	How the web console can access the OpenShift Container Platform server.
MetricsPublicURL	The public endpoint for metrics (optional).
PublicURL	URL of the the asset server.

7.2.3. Authentication and Authorization Configuration

Table 7.3. Authentication and Authorization Parameters

Parameter Name	Description
authConfig	Holds authentication and authorization configuration options.
AuthenticationCacheSiz e	Indicates how many authentication results should be cached. If 0, the default cache size is used.
AuthorizationCacheTTL	Indicates how long an authorization result should be cached. It takes a valid time duration string (e.g. "5m"). If empty, you get the default timeout. If zero (e.g. "0m"), caching is disabled.

7.2.4. Controller Configuration

Table 7.4. Controller Configuration Parameters

Parameter Name	Description
Controllers	List of the controllers that should be started. If set to none , no controllers will start automatically. The default value is * which will start all controllers. When using *, you may exclude controllers by prepending a - in front of their name. No other values are recognized at this time.
ControllerLeaseTTL	Enables controller election, instructing the master to attempt to acquire a lease before controllers start and renewing it within a number of seconds defined by this value. Setting this value non-negative forces pauseControllers=true. This value defaults off (0, or omitted) and controller election can be disabled with -1.
PauseControllers	Instructs the master to not automatically start controllers, but instead to wait until a notification to the server is received before launching them.

7.2.5. etcd Configuration

Table 7.5. etcd Configuration Parameters

Parameter Name	Description
Address	The advertised host:port for client connections to etcd.
etcdClientInfo	Contains information about how to connect to etcd.
etcdConfig	Holds the necessary configuration options for connecting with an etcd database.
etcdStorageConfig	Contains information about how API resources are stored in etcd. These values are only relevant when etcd is the backing store for the cluster.
KubernetesStoragePrefi x	The path within etcd that the Kubernetes resources will be rooted under. This value, if changed, will mean existing objects in <i>etcd</i> will no longer be located. The default value is kubernetes.io .
KubernetesStorageVersi on	The API version that Kubernetes resources in <i>etcd</i> should be serialized to. This value should not be advanced until all clients in the cluster that read from etcd have code that allows them to read the new version.
OpenShiftStoragePrefix	The path within etcd that the OpenShift Container Platform resources will be rooted under. This value, if changed, will mean existing objects in etcd will no longer be located. The default value is openshift.io .
OpenShiftStorageVersio n	API version that OS resources in <i>etcd</i> should be serialized to. This value should not be advanced until all clients in the cluster that read from <i>etcd</i> have code that allows them to read the new version.
PeerAddress	The advertised host:port for peer connections to <i>etcd</i> .
PeerServingInfo	Describes how to start serving the <i>etcd</i> peer.
ServingInfo	Describes how to start serving the etcd master.
StorageDir	The path to the <i>etcd</i> storage directory.

7.2.6. Grant Configuration

Table 7.6. Grant Configuration Parameters

Parameter Name	Description
GrantConfig	Describes how to handle grants.

Parameter Name	Description
GrantHandlerAuto	Auto-approves client authorization grant requests.
GrantHandlerDeny	Auto-denies client authorization grant requests.
GrantHandlerPrompt	Prompts the user to approve new client authorization grant requests.
Method	Determines the default strategy to use when an OAuth client requests a grant. This method will be used only if the specific OAuth client does not provide a strategy of their own. Valid grant handling methods are: • auto: always approves grant requests, useful for trusted clients • prompt: prompts the end user for approval of grant requests, useful for third-party clients • deny: always denies grant requests, useful for black-listed clients

7.2.7. Image Configuration

Table 7.7. Image Configuration Parameters

Parameter Name	Description
DisableScheduledImport	Allows scheduled background import of images to be disabled.
Format	The format of the name to be built for the system component.
ImageConfig	Holds options that describe how to build image names for system components.
ImagePolicyConfig	Controls limits and behavior for importing images.
Latest	Determines if the latest tag will be pulled from the registry.
MaxImagesBulkImportedP erRepository	Controls the number of images that are imported when a user does a bulk import of a Docker repository. This number defaults to 5 to prevent users from importing large numbers of images accidentally. Set -1 for no limit.
MaxScheduledImageImpor tsPerMinute	The maximum number of scheduled image streams that will be imported in the background per minute. The default value is 60.
ScheduledImageImportMi nimumIntervalSeconds	The minimum number of seconds that can elapse between when image streams scheduled for background import are checked against the upstream repository. The default value is 15 minutes.

7.2.8. Kubernetes Master Configuration

Table 7.8. Kubernetes Master Configuration Parameters

Parameter Name	Description
APILevels	A list of API levels that should be enabled on startup, v1 as examples.
DisabledAPIGroupVersio ns	A map of groups to the versions (or *) that should be disabled.
KubeletClientInfo	Contains information about how to connect to kubelets.
KubernetesMasterConfig	Holds the necessary configuration options for the Kubernetes master.
MasterCount	The number of expected masters that should be running. This value defaults to 1 and may be set to a positive integer, or if set to -1, indicates this is part of a cluster.
MasterIP	The public IP address of Kubernetes resources. If empty, the first result from net . InterfaceAddrs will be used.
MasterKubeConfig	File name for the .kubeconfig file that describes how to connect this node to the master.
ServicesNodePortRange	The range to use for assigning service public ports on a host. Default 30000-32767.
ServicesSubnet	The subnet to use for assigning service IPs.
StaticNodeNames	The list of nodes that are statically known.

7.2.9. Network Configuration

Choose the CIDRs in the following parameters carefully, because the IPv4 address space is shared by all users of the nodes. OpenShift Container Platform reserves CIDRs from the IPv4 address space for its own use, and reserves CIDRs from the IPv4 address space for addresses that are shared between the external user and the cluster.

Table 7.9. Network Configuration Parameters

Parameter Name	Description
ClusterNetworkCIDR	The CIDR string to specify the global overlay network's L3 space. This is reserved for the internal use of the cluster networking.

Parameter Name	Description
ExternalIPNetworkCIDRs	Controls what values are acceptable for the service external IP field. If empty, no external IP may be set. It may contain a list of CIDRs which are checked for access. If a CIDR is prefixed with !, IPs in that CIDR will be rejected. Rejections will be applied first, then the IP checked against one of the allowed CIDRs. You must ensure this range does not overlap with your nodes, pods, or service CIDRs for security reasons.
HostSubnetLength	The number of bits to allocate to each host's subnet. For example, 8 would mean a /24 network on the host.
IngressIPNetworkCIDR	Controls the range to assign ingress IPs from for services of type LoadBalancer on bare metal. It may contain a single CIDR that it will be allocated from. By default 172.46.0.0/16 is configured. For security reasons, you should ensure that this range does not overlap with the CIDRs reserved for external IPs, nodes, pods, or services.
HostSubnetLength	The number of bits to allocate to each host's subnet. For example, 8 would mean a /24 network on the host.
NetworkConfig	Provides network options for the node.
NetworkPluginName	The name of the network plug-in to use.
ServiceNetwork	The CIDR string to specify the service networks.

7.2.10. OAuth Authentication Configuration

Table 7.10. OAuth Configuration Parameters

Parameter Name	Description
AlwaysShowProviderSele ction	Forces the provider selection page to render even when there is only a single provider.
AssetPublicURL	Used for building valid client redirect URLs for external access.
Error	A path to a file containing a go template used to render error pages during the authentication or grant flow If unspecified, the default error page is used.
IdentityProviders	Ordered list of ways for a user to identify themselves.
Login	A path to a file containing a go template used to render the login page. If unspecified, the default login page is used.

Parameter Name	Description
MasterCA	CA for verifying the TLS connection back to the MasterURL.
MasterPublicURL	Used for building valid client redirect URLs for external access.
MasterURL	Used for making server-to-server calls to exchange authorization codes for access tokens.
OAuthConfig	Holds the necessary configuration options for OAuth authentication.
OAuthTemplates	Allows for customization of pages like the login page.
ProviderSelection	A path to a file containing a go template used to render the provider selection page. If unspecified, the default provider selection page is used.
SessionConfig	Holds information about configuring sessions.
Templates	Allows you to customize pages like the login page.
TokenConfig	Contains options for authorization and access tokens.

7.2.11. Project Configuration

Table 7.11. Project Configuration Parameters

Parameter Name	Description
DefaultNodeSelector	Holds default project node label selector.
ProjectConfig	Holds information about project creation and defaults.
ProjectRequestMessage	The string presented to a user if they are unable to request a project via the project request API endpoint.
ProjectRequestTemplate	The template to use for creating projects in response to projectrequest . It is in the format namespace/template and it is optional. If it is not specified, a default template is used.

7.2.12. Scheduler Configuration

Table 7.12. Scheduler Configuration Parameters

Parameter Name	Description
----------------	-------------

Parameter Name	Description
SchedulerConfigFile	Points to a file that describes how to set up the scheduler. If empty, you get the default scheduling rules

7.2.13. Security Allocator Configuration

Table 7.13. Security Allocator Parameters

Parameter Name	Description
MCSAllocatorRange	Defines the range of MCS categories that will be assigned to namespaces. The format is <prefix>/<numberoflabels>[, <maxcategory>]. The default issO/2 and will allocate from c0 to c1023, which means a total of 535k labels are available (1024 choose 2 ~ 535k). If this value is changed after startup, new projects may receive labels that are already allocated to other projects. Prefix may be any valid SELinux set of terms (including user, role, and type), although leaving them as the default will allow the server to set them automatically.</maxcategory></numberoflabels></prefix>
SecurityAllocator	Controls the automatic allocation of UIDs and MCS labels to a project. If nil, allocation is disabled.
UIDAllocatorRange	Defines the total set of Unix user IDs (UIDs) that will be allocated to projects automatically, and the size of the block each namespace gets. For example, 1000-1999/10 will allocate ten UIDs per namespace, and will be able to allocate up to 100 blocks before running out of space. The default is to allocate from 1 billion to 2 billion in 10k blocks (which is the expected size of the ranges container images will use once user namespaces are started).

7.2.14. Service Account Configuration

Table 7.14. Service Account Configuration Parameters

Parameter Name	Description
LimitSecretReferences	Controls whether or not to allow a service account to reference any secret in a namespace without explicitly referencing them.
ManagedNames	A list of service account names that will be auto-created in every namespace. If no names are specified, the ServiceAccountsController will not be started.
MasterCA	The CA for verifying the TLS connection back to the master. The service account controller will automatically inject the contents of this file into pods so they can verify connections to the master.

Parameter Name	Description
PrivateKeyFile	A file containing a PEM-encoded private RSA key, used to sign service account tokens. If no private key is specified, the service account TokensController will not be started.
PublicKeyFiles	A list of files, each containing a PEM-encoded public RSA key. If any file contains a private key, the public portion of the key is used. The list of public keys is used to verify presented service account tokens. Each key is tried in order until the list is exhausted or verification succeeds. If no keys are specified, no service account authentication will be available.
ServiceAccountConfig	Holds the necessary configuration options for a service account.

7.2.15. Serving Information Configuration

 Table 7.15. Serving Information Configuration Parameters

Parameter Name	Description
AllowRecursiveQueries	Allows the DNS server on the master to answer queries recursively. Note that open resolvers can be used for DNS amplification attacks and the master DNS should not be made accessible to public networks.
BindAddress	The ip:port to serve on.
BindNetwork	Controls limits and behavior for importing images.
CertFile	A file containing a PEM-encoded certificate.
CertInfo	TLS cert information for serving secure traffic.
ClientCA	The certificate bundle for all the signers that you recognize for incoming client certificates.
dnsConfig	Holds the necessary configuration options for DNS.
DNSDomain	Holds the domain suffix.
DNSIP	Holds the IP.
KeyFile	A file containing a PEM-encoded private key for the certificate specified by CertFile .
MasterClientConnection Overrides	Provides overrides to the client connection used to connect to the master.

Parameter Name	Description
MaxRequestsInFlight	The number of concurrent requests allowed to the server. If zero, no limit.
NamedCertificates	A list of certificates to use to secure requests to specific host names.
RequestTimeoutSecond	The number of seconds before requests are timed out. The default is 60 minutes. If -1, there is no limit on requests.
ServingInfo	The HTTP serving information for the assets.

7.2.16. Volume Configuration

Table 7.16. Volume Configuration Parameters

Parameter Name	Description
DynamicProvisioningEna bled	A boolean to enable or disable dynamic provisioning. Default is true .
FSGroup	Can be specified to enable a quota on local storage use per unique FSGroup ID. At present this is only implemented for emptyDir volumes, and if the underlying volumeDirectory is on an XFS filesystem.
LocalQuota	Contains options for controlling local volume quota on the node.
MasterVolumeConfig	Contains options for configuring volume plug-ins in the master node.
NodeVolumeConfig	Contains options for configuring volumes on the node.
VolumeConfig	Contains options for configuring volumes on the node.
VolumeDirectory	The directory that volumes are stored under.

7.2.17. Audit Configuration

Audit provides a security-relevant chronological set of records documenting the sequence of activities that have affected system by individual users, administrators, or other components of the system.

Audit works at the API server level, logging all requests coming to the server. Each audit log contains two entries:

- 1. The request line containing:
 - a. A Unique ID allowing to match the response line (see #2)
 - b. The source IP of the request
 - c. The HTTP method being invoked

- d. The original user invoking the operation
- e. The impersonated user for the operation (self meaning himself)
- f. The impersonated group for the operation (lookup meaning user's group)
- g. The namespace of the request or <none>
- h. The URI as requested
- 2. The response line containing:
 - a. The the unique ID from #1
 - b. The response code

Example output for user admin asking for a list of pods:

```
AUDIT: id="5c3b8227-4af9-4322-8a71-542231c3887b" ip="127.0.0.1" method="GET" user="admin" as="<self>" asgroups="<lookup>" namespace="default" uri="/api/v1/namespaces/default/pods" AUDIT: id="5c3b8227-4af9-4322-8a71-542231c3887b" response="200"
```

The **openshift_master_audit_config** variable enables API service auditing. It takes an array of the following options:

Table 7.17. Audit Configuration Parameters

Parameter Name	Description
enabled	A boolean to enable or disable audit logs. Default is false .
auditFilePath	File path where the requests should be logged to. If not set, logs are printed to master logs.
maximumFileRetentionDa ys	Specifies maximum number of days to retain old audit log files based on the time stamp encoded in their filename.
maximumRetainedFiles	Specifies the maximum number of old audit log files to retain.
maximumFileSizeMegabyt es	Specifies maximum size in megabytes of the log file before it gets rotated. Defaults to 100MB.

Example Audit Configuration

```
auditConfig:
   auditFilePath: "/var/log/audit-ocp.log"
   enabled: true
   maximumFileRetentionDays: 10
   maximumFileSizeMegabytes: 10
   maximumRetainedFiles: 10
```

Advanced Setup for the Audit Log

If you want more advanced setup for the audit log, you can use:

```
openshift_master_audit_config={"enabled": true}
```

The directory in auditFilePath will be created if it does not exist.

```
openshift_master_audit_config={"enabled": true, "auditFilePath":
   "/var/log/openpaas-oscp-audit/openpaas-oscp-audit.log",
   "maximumFileRetentionDays": 14, "maximumFileSizeMegabytes": 500,
   "maximumRetainedFiles": 5}
```

7.3. NODE CONFIGURATION FILES

The following *node-config.yaml* file is a sample node configuration file that was generated with the default values as of writing. You can create a new node configuration file to see the valid options for your installed version of OpenShift Container Platform.

Example 7.1. Sample Node Configuration File

```
allowDisabledDocker: false
apiVersion: v1
authConfig:
  authenticationCacheSize: 1000
  authenticationCacheTTL: 5m
  authorizationCacheSize: 1000
  authorizationCacheTTL: 5m
dnsDomain: cluster.local
dnsIP: 10.0.2.15 1
dockerConfig:
  execHandlerName: native
imageConfig:
  format: openshift/origin-${component}:${version}
  latest: false
iptablesSyncPeriod: 5s
kind: NodeConfig
masterKubeConfig: node.kubeconfig
networkConfig:
 mtu: 1450
  networkPluginName: ""
nodeIP: ""
nodeName: node1.example.com
podManifestConfig: 2
  path: "/path/to/pod-manifest-file" 3
  fileCheckIntervalSeconds: 30 4
proxyArguments:
  proxy-mode:
  - iptables 5
volumeConfig:
 localQuota:
   perFSGroup: null 6
servingInfo:
  bindAddress: 0.0.0.0:10250
  bindNetwork: tcp4
```

certFile: server.crt

clientCA: node-client-ca.crt

keyFile: server.key
namedCertificates: null

volumeDirectory: /root/openshift.local.volumes

- Configures an IP address to be prepended to a pod's /etc/resolv.conf by adding the address here.
- Allows pods to be placed directly on certain set of nodes, or on all nodes without going through the scheduler. You can then use pods to perform the same administrative tasks and support the same services on each node.
- 3 Specifies the path for the pod manifest file or directory. If it is a directory, then it is expected to contain one or more manifest files. This is used by the Kubelet to create pods on the node.
- This is the interval (in seconds) for checking the manifest file for new data. The interval must be a positive value.
- The service proxy implementation to use.
- Preliminary support for local emptyDir volume quotas, set this value to a resource quantity representing the desired quota per FSGroup, per node. (i.e. 1Gi, 512Mi, etc.) Currently requires that the *volumeDirectory* be on an XFS filesystem mounted with the 'gquota' option, and the matching security context contraint's fsGroup type set to 'MustRunAs'.

7.3.1. Pod and Node Configuration

Table 7.18. Pod and Node Configuration Parameters

Parameter Name	Description
NodeConfig	The fully specified configuration starting an OpenShift Container Platform node.
NodeIP	Node may have multiple IPs, so this specifies the IP to use for pod traffic routing. If not specified, network parse/lookup on the nodeName is performed and the first non-loopback address is used.
NodeName	The value used to identify this particular node in the cluster. If possible, this should be your fully qualified hostname. If you are describing a set of static nodes to the master, this value must match one of the values in the list.
PodEvictionTimeout	Controls grace period for deleting pods on failed nodes. It takes valid time duration string. If empty, you get the default pod eviction timeout.
ProxyClientInfo	Specifies the client cert/key to use when proxying to pods.

7.3.2. Docker Configuration

Table 7.19. Docker Configuration Parameters

Parameter Name	Description
AllowDisabledDocker	If true, the kubelet will ignore errors from Docker. This means that a node can start on a machine that does not have docker started.
DockerConfig	Holds Docker related configuration options
ExecHandlerName	The handler to use for executing commands in Docker containers.

7.3.3. Parallel Image Pulls with Docker 1.9+

If you are using Docker 1.9+, you may want to consider enabling parallel image pulling, as the default is to pull images one at a time.

NOTE

There is a potential issue with data corruption prior to Docker 1.9. However, starting with 1.9, the corruption issue is resolved and it is safe to switch to parallel pulls.

kubeletArguments:
 serialize-image-pulls:
 "false" 1

1 Change to true to disable parallel pulls. (This is the default config)

7.4. PASSWORDS AND OTHER SENSITIVE DATA

For some authentication configurations, an LDAP bindPassword or OAuth clientSecret value is required. Instead of specifying these values directly in the master configuration file, these values may be provided as environment variables, external files, or in encrypted files.

Environment Variable Example

bindPassword:
 env: BIND_PASSWORD_ENV_VAR_NAME

External File Example

...
bindPassword:
 file: bindPassword.txt

Encrypted External File Example

... bindPassword: file: bindPassword.encrypted
keyFile: bindPassword.key

To create the encrypted file and key file for the above example:

\$ oadm ca encrypt --genkey=bindPassword.key --out=bindPassword.encrypted
> Data to encrypt: B1ndPassOrd!

WARNING

Encrypted data is only as secure as the decrypting key. Care should be taken to limit filesystem permissions and access to the key file.

7.5. CREATING NEW CONFIGURATION FILES

When defining an OpenShift Container Platform configuration from scratch, start by creating new configuration files.

For master host configuration files, use the **openshift** start command with the --write-config option to write the configuration files. For node hosts, use the **oadm** create-node-config command to write the configuration files.

The following commands write the relevant launch configuration file(s), certificate files, and any other necessary files to the specified --write-config or --node-dir directory.

Generated certificate files are valid for two years, while the certification authority (CA) certificate is valid for five years. This can be altered with the --expire-days and --signer-expire-days options, but for security reasons, it is recommended to not make them greater than these values.

To create configuration files for an all-in-one server (a master and a node on the same host) in the specified directory:

```
$ openshift start --write-config=/openshift.local.config
```

To create a master configuration file and other required files in the specified directory:

```
$ openshift start master --write-config=/openshift.local.config/master
```

To create a node configuration file and other related files in the specified directory:

```
$ oadm create-node-config \
    --node-dir=/openshift.local.config/node-<node_hostname> \
    --node=<node_hostname> \
    --hostnames=<node_hostname>,<ip_address> \
    --certificate-authority="/path/to/ca.crt" \
    --signer-cert="/path/to/ca.crt" \
    --signer-key="/path/to/ca.key"
    --signer-serial="/path/to/ca.serial.txt"
    --node-client-certificate-authority="/path/to/ca.crt"
```

_

When creating node configuration files, the **--hostnames** option accepts a comma-delimited list of every host name or IP address you want server certificates to be valid for.

7.6. LAUNCHING SERVERS USING CONFIGURATION FILES

Once you have modified the master and/or node configuration files to your specifications, you can use them when launching servers by specifying them as an argument. Keep in mind that if you specify a configuration file, none of the other command line options you pass are respected.

To launch an all-in-one server using a master configuration and a node configuration file:

```
$ openshift start --master-config=/openshift.local.config/master/master-
config.yaml --node-config=/openshift.local.config/node-
<node_hostname>/node-config.yaml
```

To launch a master server using a master configuration file:

```
$ openshift start master --config=/openshift.local.config/master/master-
config.yaml
```

To launch a node server using a node configuration file:

```
$ openshift start node --config=/openshift.local.config/node-
<node_hostname>/node-config.yaml
```

7.7. CONFIGURING LOGGING LEVELS

OpenShift Container Platform uses the systemd-journald.service to collect log messages for debugging, using five log message severities. The logging levels are based on Kubernetes logging conventions, as follows:

Table 7.20. Log Level Options

Option	Description
0	Errors and warnings only
2	Normal information
4	Debugging-level information
6	API-level debugging information (request / response)
8	Body-level API debugging information

You can control which INFO messages are logged by setting the loglevel option in the in /etc/sysconfig/atomic-openshift-node or /etc/sysconfig/atomic-openshift-master file. Configuring the logs to collect all messages can lead to large logs that are difficult to interpret and can take up excessive space. Collecting all messages should only be used in debug situations.

NOTE

Messages with FATAL, ERROR, WARNING and some INFO severities appear in the logs regardless of the log configuration.

You can view logs for the master or the node system using the following command:

```
# journalctl -r -u <journal_name>
```

Use the -r option to show the newest entries first.

For example:

```
# journalctl -r -u atomic-openshift-master.service
# journalctl -r -u atomic-openshift-node.service
```

To change the logging level:

- 1. Edit the /etc/sysconfig/atomic-openshift-master file for the master or /etc/sysconfig/atomic-openshift-node file for the nodes.
- 2. Enter a value from the **Log Level Options** table above in the **OPTIONS=--loglevel=** field. For example:

```
OPTIONS=--loglevel=4
```

3. Restart the master or node host as appropriate:

```
# systemctl restart atomic-openshift-master
# systemctl restart atomic-openshift-node
```

After the restart, all new log messages will conform to the new setting. Older messages do not change.

NOTE

The default log level can be set using the Advanced Install. For more information, see Cluster Variables.

The following examples are excerpts from a master **journald** log at various log levels. Timestamps and system information have been removed from these examples.

Excerpt of journalctl -u atomic-openshift-master.service output at loglevel=0

```

CHAPTER 8. ADDING HOSTS TO AN EXISTING CLUSTER

8.1. OVERVIEW

Depending on how your OpenShift Container Platform cluster was installed, you can add new hosts (either nodes or masters) to your installation by using the install tool for quick installations, or by using the *scaleup.yml* playbook for advanced installations.

8.2. ADDING HOSTS USING THE QUICK INSTALLER TOOL

If you used the quick install tool to install your OpenShift Container Platform cluster, you can use the quick install tool to add a new node host to your existing cluster.

NOTE

Currently, you can not use the quick installer tool to add new master hosts. You must use the advanced installation method to do so.

If you used the installer in either interactive or unattended mode, you can re-run the installation as long as you have an installation configuration file at ~/.config/openshift/installer.cfg.yml (or specify a different location with the -c option).

IMPORTANT

The recommended maximum number of nodes is 300.

To add nodes to your installation:

1. Ensure you have the latest installer and playbooks by updating the **atomic-openshift-utils** package:

```
# yum update atomic-openshift-utils
```

2. Run the installer with the scaleup subcommand in interactive or unattended mode:

```
# atomic-openshift-installer [-u] [-c </path/to/file>] scaleup
```

3. The installer detects your current environment and allows you to add additional nodes:

```
*** Installation Summary ***

Hosts:
- 100.100.1.1
- OpenShift master
- OpenShift node
- Etcd (Embedded)
- Storage

Total OpenShift masters: 1
Total OpenShift nodes: 1
```

- - -

We have detected this previously installed OpenShift environment.

This tool will guide you through the process of adding additional nodes to your cluster.

Are you ready to continue? [y/N]:

Choose (y) and follow the on-screen instructions to complete your desired task.

8.3. ADDING HOSTS USING THE ADVANCED INSTALL

If you installed using the advanced install, you can add new hosts to your cluster by running the *scaleup.yml* playbook. This playbook queries the master, generates and distributes new certificates for the new hosts, then runs the configuration playbooks on the new hosts only. Before running the *scaleup.yml* playbook, complete all prerequisite host preparation steps.

This process is similar to re-running the installer in the quick installation method to add nodes, however you have more configuration options available when using the advanced method and when running the playbooks directly.

You must have an existing inventory file (for example, /etc/ansible/hosts) that is representative of your current cluster configuration in order to run the scaleup.yml playbook. If you previously used the atomic-openshift-installer command to run your installation, you can check ~/.config/openshift/hosts (previously located at ~/.config/openshift/.ansible/hosts) for the last inventory file that the installer generated, and use or modify that as needed as your inventory file. You must then specify the file location with -i when calling ansible-playbook later.

IMPORTANT

The recommended maximum number of nodes is 300.

To add a host to an existing cluster:

1. Ensure you have the latest playbooks by updating the atomic-openshift-utils package:

```
# yum update atomic-openshift-utils
```

2. Edit your /etc/ansible/hosts file and add new_<host_type> to the [OSEv3:children] section: For example, to add a new node host, add new_nodes:

```
[OSEv3:children]
masters
nodes
new_nodes
```

To add new master hosts, add new_masters.

3. Create a [new_<host_type>] section much like an existing section, specifying host information for any new hosts you want to add. For example, when adding a new node:

```
[nodes]
master[1:3].example.com
```

```
node1.example.com openshift_node_labels="{'region': 'primary',
    'zone': 'east'}"
node2.example.com openshift_node_labels="{'region': 'primary',
    'zone': 'west'}"
infra-node1.example.com openshift_node_labels="{'region': 'infra',
    'zone': 'default'}"
infra-node2.example.com openshift_node_labels="{'region': 'infra',
    'zone': 'default'}"

[new_nodes]
node3.example.com openshift_node_labels="{'region': 'primary',
    'zone': 'west'}"
```

See Configuring Host Variables for more options.

When adding new masters, hosts added to the [new_masters] section must also be added to the [new_nodes] section. This ensures the new master host is part of the OpenShift SDN.

```
[masters]
master[1:2].example.com
[new_masters]
master3.example.com
[nodes]
master[1:2].example.com
node1.example.com openshift_node_labels="{'region': 'primary',
'zone': 'east'}"
node2.example.com openshift_node_labels="{'region': 'primary',
'zone': 'west'}"
infra-node1.example.com openshift_node_labels="{'region': 'infra',
'zone': 'default'}"
infra-node2.example.com openshift_node_labels="{'region': 'infra',
'zone': 'default'}"
[new_nodes]
master3.example.com
```

Masters are also automatically marked as unschedulable for pod placement by the installer.

IMPORTANT

If you label a master host with the **region=infra** label and have no other dedicated infrastructure nodes, you must also explicitly mark the host as schedulable by adding **openshift_schedulable=true** to the entry. Otherwise, the registry and router pods cannot be placed anywhere.

4. Run the scaleup.yml playbook. If your inventory file is located somewhere other than the default of /etc/ansible/hosts, specify the location with the -i option.

For additional nodes:

```
# ansible-playbook [-i /path/to/file] \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
node/scaleup.yml
```

For additional masters:

```
# ansible-playbook [-i /path/to/file] \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
master/scaleup.yml
```

- 5. After the playbook completes successfully, verify the installation.
- 6. Finally, move any hosts you had defined in the [new_<host_type>] section into their appropriate section (but leave the [new_<host_type>] section definition itself in place) so that subsequent runs using this inventory file are aware of the nodes but do not handle them as new nodes. For example, when adding new nodes:

```
[nodes]
master[1:3].example.com
node1.example.com openshift_node_labels="{'region': 'primary',
    'zone': 'east'}"
node2.example.com openshift_node_labels="{'region': 'primary',
    'zone': 'west'}"
node3.example.com openshift_node_labels="{'region': 'primary',
    'zone': 'west'}"
infra-node1.example.com openshift_node_labels="{'region': 'infra',
    'zone': 'default'}"
infra-node2.example.com openshift_node_labels="{'region': 'infra',
    'zone': 'default'}"
[new_nodes]
```

CHAPTER 9. LOADING THE DEFAULT IMAGE STREAMS AND TEMPLATES

9.1. OVERVIEW

Your OpenShift Container Platform installation includes useful sets of Red Hat-provided image streams and templates to make it easy for developers to create new applications. By default, the quick and advanced installation methods automatically create these sets in the openshift project, which is a default global project to which all users have view access.

9.2. OFFERINGS BY SUBSCRIPTION TYPE

Depending on the active subscriptions on your Red Hat account, the following sets of image streams and templates are provided and supported by Red Hat. Contact your Red Hat sales representative for further subscription details.

9.2.1. OpenShift Container Platform Subscription

The core set of image streams and templates are provided and supported with an active *OpenShift Container Platform subscription*. This includes the following technologies:

Туре	Technology
Languages & Frameworks	• .NET Core
	• Node.js
	• Peri
	• PHP
	Python
	• Ruby
Databases	MongoDB
	MySQL
	PostgreSQL
Middleware Services	Red Hat JBoss Web Server(Tomcat)
	Red Hat Single Sign-on
Other Services	• Jenkins

9.2.2. xPaaS Middleware Add-on Subscriptions

Support for xPaaS middleware images are provided by xPaaS Middleware add-on subscriptions which are separate subscriptions for each xPaaS product. If the relevant subscription is active on your account, image streams and templates are provided and supported for the following technologies:

Туре	Technology
Middleware Services	 Red Hat JBoss A-MQ Red Hat JBoss BPM Suite Intelligent Process Server Red Hat JBoss BRMS Decision Server Red Hat JBoss Data Grid Red Hat JBoss EAP Red Hat JBoss Fuse Integration Services

9.3. BEFORE YOU BEGIN

Before you consider performing the tasks in this topic, confirm if these image streams and templates are already registered in your OpenShift Container Platform cluster by doing one of the following:

- Log into the web console and click **Add to Project**.
- List them for the **openshift** project using the CLI:

```
$ oc get is -n openshift
$ oc get templates -n openshift
```

If the default image streams and templates are ever removed or changed, you can follow this topic to create the default objects yourself. Otherwise, the following instructions are not necessary.

9.4. PREREQUISITES

Before you can create the default image streams and templates:

- The integrated Docker registry service must be deployed in your OpenShift Container Platform installation.
- You must be able to run the oc create command with cluster-admin privileges, because they operate on the default openshiftproject.
- You must have installed the **atomic-openshift-utils** RPM package. See Software Prerequisites for instructions.
- Define shell variables for the directories containing image streams and templates. This significantly shortens the commands in the following sections. To do this:

```
$ IMAGESTREAMDIR="/usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/image-streams";
```

```
XPAASSTREAMDIR="/usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/xpaas-streams";

XPAASTEMPLATES="/usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/xpaas-
templates";

DBTEMPLATES="/usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/db-templates";

QSTEMPLATES="/usr/share/ansible/openshift-
ansible/roles/openshift_examples/files/examples/v1.5/quickstart-
templates"
```

9.5. CREATING IMAGE STREAMS FOR OPENSHIFT CONTAINER PLATFORM IMAGES

If your node hosts are subscribed using Red Hat Subscription Manager and you want to use the core set of image streams that used Red Hat Enterprise Linux (RHEL) 7 based images:

```
$ oc create -f $IMAGESTREAMDIR/image-streams-rhel7.json -n openshift
```

Alternatively, to create the core set of image streams that use the CentOS 7 based images:

```
$ oc create -f $IMAGESTREAMDIR/image-streams-centos7.json -n openshift
```

Creating both the CentOS and RHEL sets of image streams is not possible, because they use the same names. To have both sets of image streams available to users, either create one set in a different project, or edit one of the files and modify the image stream names to make them unique.

9.6. CREATING IMAGE STREAMS FOR XPAAS MIDDLEWARE IMAGES

The xPaaS Middleware image streams provide images for JBoss EAP, JBoss JWS, JBoss A-MQ, JBoss Fuse Integration Services, Decision Server, and JBoss Data Grid. They can be used to build applications for those platforms using the provided templates.

To create the xPaaS Middleware set of image streams:

\$ oc create -f \$XPAASSTREAMDIR/jboss-image-streams.json -n openshift

NOTE

Access to the images referenced by these image streams requires the relevant xPaaS Middleware subscriptions.

9.7. CREATING DATABASE SERVICE TEMPLATES

The database service templates make it easy to run a database image which can be utilized by other components. For each database (MongoDB, MySQL, and PostgreSQL), two templates are defined.

One template uses ephemeral storage in the container which means data stored will be lost if the container is restarted, for example if the pod moves. This template should be used for demonstration purposes only.

The other template defines a persistent volume for storage, however it requires your OpenShift Container Platform installation to have persistent volumes configured.

To create the core set of database templates:

```
$ oc create -f $DBTEMPLATES -n openshift
```

After creating the templates, users are able to easily instantiate the various templates, giving them quick access to a database deployment.

9.8. CREATING INSTANT APP AND QUICKSTART TEMPLATES

The Instant App and Quickstart templates define a full set of objects for a running application. These include:

- Build configurations to build the application from source located in a GitHub public repository
- Deployment configurations to deploy the application image after it is built.
- Services to provide load balancing for the application pods.
- Routes to provide external access to the application.

Some of the templates also define a database deployment and service so the application can perform database operations.

NOTE

The templates which define a database use ephemeral storage for the database content. These templates should be used for demonstration purposes only as all database data will be lost if the database pod restarts for any reason.

Using these templates, users are able to easily instantiate full applications using the various language images provided with OpenShift Container Platform. They can also customize the template parameters during instantiation so that it builds source from their own repository rather than the sample repository, so this provides a simple starting point for building new applications.

To create the core Instant App and Quickstart templates:

```
$ oc create -f $QSTEMPLATES -n openshift
```

There is also a set of templates for creating applications using various xPaaS Middleware products (JBoss EAP, JBoss JWS, JBoss A-MQ, JBoss Fuse Integration Services, Decision Server, and JBoss Data Grid), which can be registered by running:

```
$ oc create -f $XPAASTEMPLATES -n openshift
```

NOTE

The xPaaS Middleware templates require the xPaaS Middleware image streams, which in turn require the relevant xPaaS Middleware subscriptions.

NOTE

The templates which define a database use ephemeral storage for the database content. These templates should be used for demonstration purposes only as all database data will be lost if the database pod restarts for any reason.

9.9. WHAT'S NEXT?

With these artifacts created, developers can now log into the web console and follow the flow for creating from a template. Any of the database or application templates can be selected to create a running database service or application in the current project. Note that some of the application templates define their own database services as well.

The example applications are all built out of GitHub repositories which are referenced in the templates by default, as seen in the SOURCE_REPOSITORY_URL parameter value. Those repositories can be forked, and the fork can be provided as the SOURCE_REPOSITORY_URL parameter value when creating from the templates. This allows developers to experiment with creating their own applications.

You can direct your developers to the Using the Instant App and Quickstart Templates section in the Developer Guide for these instructions.

CHAPTER 10. CONFIGURING CUSTOM CERTIFICATES

10.1. OVERVIEW

Administrators can configure custom serving certificates for the public host names of the OpenShift Container Platform API and web console. This can be done during an advanced installation or configured after installation.

10.2. CONFIGURING CUSTOM CERTIFICATES WITH ANSIBLE

During advanced installations, custom certificates can be configured using the openshift_master_named_certificates and openshift_master_overwrite_named_certificates parameters, which are configurable in the inventory file. More details are available about configuring custom certificates with Ansible.

Example 10.1. Example Custom Certificate Configuration with Ansible

```
# Configure custom named certificates
# NOTE: openshift_master_named_certificates is cached on masters and is
# additive fact, meaning that each run with a different set of
certificates
# will add the newly provided certificates to the cached set of
certificates.
# An optional CA may be specified for each named certificate. CAs will
# be added to the OpenShift CA bundle which allows for the named
# certificate to be served for internal cluster communication.
# If you would like openshift master named certificates to be
overwritten with
# the provided value, specify
openshift_master_overwrite_named_certificates.
openshift_master_overwrite_named_certificates=true
# Provide local certificate paths which will be deployed to masters
openshift_master_named_certificates=[{"certfile":
"/path/on/host/to/custom1.crt", "keyfile":
"/path/on/host/to/custom1.key", "cafile": "/path/on/host/to/custom-
ca1.crt"}]
#
# Detected names may be overridden by specifying the "names" key
#openshift_master_named_certificates=[{"certfile":
"/path/on/host/to/custom1.crt", "keyfile":
"/path/on/host/to/custom1.key", "names": ["public-master-host.com"],
"cafile": "/path/on/host/to/custom-ca1.crt"}]
```

10.3. CONFIGURING CUSTOM CERTIFICATES

In the master configuration file you can list the namedCertificates section in the assetConfig.servingInfo section so the custom certificate serves up for the web console, and in the servingInfo section so the custom certificate serves up for the CLI and other API calls. Multiple

certificates can be configured this way and each certificate may be associated with multiple host names or wildcards.

A default certificate must be configured in the servingInfo.certFile and servingInfo.keyFile configuration sections in addition to namedCertificates.

NOTE

The namedCertificates section should only be configured for the host name associated with the masterPublicURL, assetConfig.publicURL, and oauthConfig.assetPublicURL settings. Using a custom serving certificate for the host name associated with the masterURL will result in TLS errors as infrastructure components will attempt to contact the master API using the internal masterURL host.

Example 10.2. Custom Certificates Configuration

```
servingInfo:
...
namedCertificates:
- certFile: custom.crt
   keyFile: custom.key
   names:
- "customhost.com"
- "api.customhost.com"
- "console.customhost.com"
- certFile: wildcard.crt
   keyFile: wildcard.key
   names:
- "*.wildcardhost.com"
...
```

Relative paths are resolved relative to the master configuration file. Restart the server to pick up the configuration changes.

CHAPTER 11. REDEPLOYING CERTIFICATES

11.1. OVERVIEW

OpenShift Container Platform uses certificates to provide secure connections for the following components:

- masters (API server and controllers)
- etcd
- nodes
- registry
- router

You can use Ansible playbooks provided with the installer to automate checking expiration dates for cluster certificates. Playbooks are also provided to automate backing up and redeploying these certificates, which can fix common certificate errors.

Possible use cases for redeploying certificates include:

- The installer detected the wrong host names and the issue was identified too late.
- The certificates are expired and you need to update them.
- You have a new CA and want to create certificates using it instead.

11.2. CHECKING CERTIFICATE EXPIRATIONS

You can use the installer to warn you about any certificates expiring within a configurable window of days and notify you about any certificates that have already expired. Certificate expiry playbooks use the Ansible role openshift_certificate_expiry.

Certificates examined by the role include:

- Master and node service certificates
- Router and registry service certificates from etcd secrets
- Master, node, router, registry, and kubeconfig files for cluster-admin users
- etcd certificates (including embedded)

11.2.1. Role Variables

The openshift_certificate_expiry role uses the following variables:

Table 11.1. Core Variables

Variable Name	Default Value	Description
openshift_certificate_expiry _config_base	/etc/origin	Base OpenShift Container Platform configuration directory.
openshift_certificate_expiry _warning_days	30	Flag certificates that will expire in this many days from now.
openshift_certificate_expiry _show_all	no	Include healthy (non-expired and non- warning) certificates in results.

Table 11.2. Optional Variables

Variable Name	Default Value	Description
openshift_certificate_expiry _generate_html_report	no	Generate an HTML report of the expiry check results.
openshift_certificate_expiry _html_report_path	/tmp/cert- expiry- report.html	The full path for saving the HTML report.
openshift_certificate_expiry _save_json_results	no	Save expiry check results as a JSON file.
openshift_certificate_expiry _json_results_path	/tmp/cert- expiry- report.json	The full path for saving the JSON report.

11.2.2. Running Certificate Expiration Playbooks

The OpenShift Container Platform installer provides a set of example certificate expiration playbooks, using different sets of configuration for the openshift_certificate_expiry role.

These playbooks must be used with an inventory file that is representative of the cluster. For best results, run ansible-playbook with the -v option.

Using the *easy-mode.yaml* example playbook, you can try the role out before tweaking it to your specifications as needed. This playbook:

- Produces JSON and stylized HTML reports in /tmp/.
- Sets the warning window very large, so you will almost always get results back.
- Includes all certificates (healthy or not) in the results.

easy-mode.yaml Playbook

name: Check cert expirys hosts: nodes:masters:etcd

become: yes

```
gather_facts: no
vars:
   openshift_certificate_expiry_warning_days: 1500
   openshift_certificate_expiry_save_json_results: yes
   openshift_certificate_expiry_generate_html_report: yes
   openshift_certificate_expiry_show_all: yes
roles:
   - role: openshift_certificate_expiry
```

To run the *easy-mode.yaml* playbook:

```
$ ansible-playbook -v -i <inventory_file> \
    /usr/share/ansible/openshift-
ansible/playbooks/certificate_expiry/easy-mode.yaml
```

Other Example Playbooks

The other example playbooks are also available to run directly out of the /usr/share/ansible/openshift-ansible/playbooks/certificate_expiry/ directory.

Table 11.3. Other Example Playbooks

File Name	Usage
default.yaml	Produces the default behavior of the openshift_certificate_expiry role.
html_and_json_default_paths.yaml	Generates HTML and JSON artifacts in their default paths.
longer_warning_period.yaml	Changes the expiration warning window to 1500 days.
longer-warning-period-json-results.yaml	Changes the expiration warning window to 1500 days and saves the results as a JSON file.

To run any of these example playbooks:

```
$ ansible-playbook -v -i <inventory_file> \
    /usr/share/ansible/openshift-
ansible/playbooks/certificate_expiry/<playbook>
```

11.2.3. Output Formats

As noted above, there are two ways to format your check report. In JSON format for machine parsing, or as a stylized HTML page for easy skimming.

HTML Report

An example of an HTML report is provided with the installer. You can open the following file in your browser to view it:

/usr/share/ansible/openshift-ansible/roles/openshift_certificate_expiry/examples/cert-expiry-report.html

JSON Report

There are two top-level keys in the saved JSON results: data and summary.

The data key is a hash where the keys are the names of each host examined and the values are the check results for the certificates identified on each respective host.

The **summary** key is a hash that summarizes the total number of certificates:

- examined on the entire cluster
- that are OK
- expiring within the configured warning window
- already expired

For an example of the full JSON report, see /usr/share/ansible/openshift-ansible/roles/openshift_certificate_expiry/examples/cert-expiry-report.json.

The summary from the JSON data can be easily checked for warnings or expirations using a variety of command-line tools. For example, using grep you can look for the word summary and print out the two lines after the match (-A2):

```
$ grep -A2 summary /tmp/cert-expiry-report.json
"summary": {
    "warning": 16,
    "expired": 0
```

If available, the jq tool can also be used to pick out specific values. The first two examples below show how to select just one value, either warning or expired. The third example shows how to select both values at once:

```
$ jq '.summary.warning' /tmp/cert-expiry-report.json
16

$ jq '.summary.expired' /tmp/cert-expiry-report.json
0

$ jq '.summary.warning,.summary.expired' /tmp/cert-expiry-report.json
16
0
```

11.3. REDEPLOYING CERTIFICATES

Use the following playbooks to redeploy master, etcd, node, registry, and router certificates on all relevant hosts. You can redeploy all of them at once using the current CA, redeploy certificates for specific components only, or redeploy a newly generated or custom CA on its own.

Just like the certificate expiry playbooks, these playbooks must be run with an inventory file that is representative of the cluster.

In particular, the inventory must specify or override all host names and IP addresses set via the following variables such that they match the current cluster configuration:

• openshift_hostname

- openshift_public_hostname
- openshift_ip
- openshift_public_ip
- openshift_master_cluster_hostname
- openshift_master_cluster_public_hostname

The playbooks you need are provided by:

yum install atomic-openshift-utils

NOTE

The validity (length in days until they expire) for any certificates auto-generated while redeploying can be configured via Ansible as well. See Configuring Certificate Validity.

11.3.1. Redeploying All Certificates Using the Current OpenShift Container Platform and etcd CA

The *redeploy-certificates.yml* playbook does *not* regenerate the OpenShift Container Platform CA certificate. New master, etcd, node, registry, and router certificates are created using the current CA certificate to sign new certificates.

This also includes serial restarts of:

- etcd
- master services
- node services

To redeploy master, etcd, and node certificates using the current OpenShift Container Platform CA, run this playbook, specifying your inventory file:

```
$ ansible-playbook -i <inventory_file> \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
cluster/redeploy-certificates.yml
```

11.3.2. Redeploying a New or Custom OpenShift Container Platform CA

The *redeploy-openshift-ca.yml* playbook redeploys the OpenShift Container Platform CA certificate by generating a new CA certificate and distributing an updated bundle to all components including client *kubeconfig* files and the node's database of trusted CAs (the CA-trust).

This also includes serial restarts of:

- master services
- node services
- docker

Additionally, you can specify a custom CA certificate when redeploying certificates instead of relying on a CA generated by OpenShift Container Platform.

When the master services are restarted, the registry and routers can continue to communicate with the master without being redeployed because the master's serving certificate is the same, and the CA the registry and routers have are still valid.

To redeploy a newly generated or custom CA:

1. If you want to use a custom CA, set the following variable in your inventory file:

```
# Configure custom ca certificate
# NOTE: CA certificate will not be replaced with existing clusters.
# This option may only be specified when creating a new cluster or
# when redeploying cluster certificates with the redeploy-
certificates
# playbook.
openshift_master_ca_certificate={'certfile': '</path/to/ca.crt>',
    'keyfile': '</path/to/ca.key>'}
```

If you do not set the above, then the current CA will be regenerated in the next step.

2. Run the redeploy-openshift-ca.yml playbook, specifying your inventory file:

```
$ ansible-playbook -i <inventory_file> \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
cluster/redeploy-openshift-ca.yml
```

With the new OpenShift Container Platform CA in place, you can then use the *redeploy-certificates.yml* playbook at your discretion whenever you want to redeploy certificates signed by the new CA on all components.

11.3.3. Redeploying a New etcd CA

The *redeploy-etcd-ca.yml* playbook redeploys the etcd CA certificate by generating a new CA certificate and distributing an updated bundle to all etcd peers and master clients.

This also includes serial restarts of:

- etcd
- master services

NOTE

The *redeploy-etcd-ca.yml* playbook is only available for OpenShift Container Platform v3.5.91-1 and above.

To redeploy a newly generated etcd CA:

1. Run the *redeploy-etcd-ca.yml* playbook, specifying your inventory file:

```
$ ansible-playbook -i <inventory_file> \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
cluster/redeploy-etcd-ca.yml
```

_

With the new etcd CA in place, you can then use the *redeploy-etcd-certificates.yml* playbook at your discretion whenever you want to redeploy certificates signed by the new etcd CA on etcd peers and master clients. Alternatively, you can use the *redeploy-certificates.yml* playbook to redeploy certificates for OpenShift Container Platform components in addition to etcd peers and master clients.

11.3.4. Redeploying Master Certificates Only

The *redeploy-master-certificates.yml* playbook only redeploys master certificates. This also includes serial restarts of master services.

To redeploy master certificates, run this playbook, specifying your inventory file:

```
$ ansible-playbook -i <inventory_file> \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
cluster/redeploy-master-certificates.yml
```

11.3.5. Redeploying etcd Certificates Only

The *redeploy-etcd-certificates.yml* playbook only redeploys etcd certificates including master client certificates.

This also include serial restarts of:

- etcd
- master services.

To redeploy etcd certificates, run this playbook, specifying your inventory file:

```
$ ansible-playbook -i <inventory_file> \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
cluster/redeploy-etcd-certificates.yml
```

11.3.6. Redeploying Node Certificates Only

The *redeploy-node-certificates.yml* playbook only redeploys node certificates. This also include serial restarts of node services.

To redeploy node certificates, run this playbook, specifying your inventory file:

```
$ ansible-playbook -i <inventory_file> \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
cluster/redeploy-node-certificates.yml
```

11.3.7. Redeploying Registry or Router Certificates Only

The *redeploy-registry-certificates.yml* and *redeploy-router-certificates.yml* playbooks replace installer-created certificates for the registry and router. If custom certificates are in use for these components, see Redeploying Custom Registry or Router Certificates to replace them manually.

11.3.7.1. Redeploying Registry Certificates Only

To redeploy registry certificates, run the following playbook, specifying your inventory file:

```
$ ansible-playbook -i <inventory_file> \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
cluster/redeploy-registry-certificates.yml
```

11.3.7.2. Redeploying Router Certificates Only

To redeploy router certificates, run the following playbook, specifying your inventory file:

```
$ ansible-playbook -i <inventory_file> \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
cluster/redeploy-router-certificates.yml
```

11.3.8. Redeploying Custom Registry or Router Certificates

When nodes are evacuated due to a redeployed CA, registry and router pods are restarted. If the registry and router certificates were not also redeployed with the new CA, this can cause outages because they cannot reach the masters using their old certificates.

The playbooks for redeploying certificates cannot redeploy custom registry or router certificates, so to address this issue, you can manually redeploy the registry and router certificates.

11.3.8.1. Redeploying Registry Certificates Manually

To redeploy registry certificates manually, you must add new registry certificates to a secret named registry-certificates, then redeploy the registry:

1. Switch to the **default** project for the remainder of these steps:

```
$ oc project default
```

- If your registry was initially created on OpenShift Container Platform 3.1 or earlier, it may still be using environment variables to store certificates (which has been deprecated in favor of using secrets).
 - a. Run the following and look for the OPENSHIFT_CA_DATA, OPENSHIFT_CERT_DATA, OPENSHIFT_KEY_DATA environment variables:

```
$ oc env dc/docker-registry --list
```

b. If they do not exist, skip this step. If they do, create the following ClusterRoleBinding:

```
$ cat <<EOF |
apiVersion: v1
groupNames: null
kind: ClusterRoleBinding
metadata:
   creationTimestamp: null
   name: registry-registry-role
roleRef:
   kind: ClusterRole
   name: system:registry</pre>
```

```
subjects:
- kind: ServiceAccount
  name: registry
  namespace: default
userNames:
- system:serviceaccount:default:registry
EOF
oc create -f -
```

Then, run the following to remove the environment variables:

```
$ oc env dc/docker-registry OPENSHIFT_CA_DATA-
OPENSHIFT_CERT_DATA- OPENSHIFT_KEY_DATA- OPENSHIFT_MASTER-
```

3. Set the following environment variables locally to make later commands less complex:

```
$ REGISTRY_IP=`oc get service docker-registry -o
jsonpath='{.spec.clusterIP}'`
$ REGISTRY_HOSTNAME=`oc get route/docker-registry -o
jsonpath='{.spec.host}'`
```

4. Create new registry certificates:

```
$ oc adm ca create-server-cert \
    --signer-cert=/etc/origin/master/ca.crt \
    --signer-key=/etc/origin/master/ca.key \
    --hostnames=$REGISTRY_IP, docker-
registry.default.svc.cluster.local,$REGISTRY_HOSTNAME \
    --cert=/etc/origin/master/registry.crt \
    --key=/etc/origin/master/registry.key \
    --signer-serial=/etc/origin/master/ca.serial.txt
```

5. Update the registry-certificates secret with the new registry certificates:

```
$ oc secret new registry-certificates \
   /etc/origin/master/registry.crt \
   /etc/origin/master/registry.key \
   -o json | oc replace -f -
```

6. Redeploy the registry:

```
$ oc deploy dc/docker-registry --latest
```

11.3.8.2. Redeploying Router Certificates Manually

When routers are initially deployed, an annotation is added to the router's service that automatically creates a service serving certificate secret.

To redeploy router certificates manually, that service serving certificate can be triggered to be recreated by deleting the secret, removing and re-adding annotations to the **router** service, then redeploying the router:

1. Switch to the **default** project for the remainder of these steps:

\$ oc project default

- 2. If your router was initially created on OpenShift Container Platform 3.1 or earlier, it may still be using environment variables to store certificates (which has been deprecated in favor of using service serving certificate secret).
 - a. Run the following and look for the OPENSHIFT_CA_DATA, OPENSHIFT_CERT_DATA, OPENSHIFT_KEY_DATA environment variables:

```
$ oc env dc/router --list
```

b. If they do not exist, skip this step. If they do, create the following ClusterRoleBinding:

```
$ cat <<EOF |
apiVersion: v1
groupNames: null
kind: ClusterRoleBinding
metadata:
  creationTimestamp: null
  name: router-router-role
roleRef:
  kind: ClusterRole
  name: system:router
subjects:
- kind: ServiceAccount
  name: router
  namespace: default
userNames:
- system:serviceaccount:default:router
E0F
oc create -f -
```

Then, run the following to remove the environment variables:

```
$ oc env dc/router OPENSHIFT_CA_DATA- OPENSHIFT_KEY_DATA-
OPENSHIFT_MASTER-
```

3. Delete the router-certs secret:

```
$ oc delete secret router-certs
```

4. Remove the following annotations from the router service:

```
$ oc annotate service router \
    service.alpha.openshift.io/serving-cert-secret-name- \
    service.alpha.openshift.io/serving-cert-signed-by-
```

5. Re-add the annotations:

```
$ oc annotate service router \
    service.alpha.openshift.io/serving-cert-secret-name=router-certs
```

6. Redeploy the router:

\$ oc deploy dc/router --latest

CHAPTER 12. CONFIGURING AUTHENTICATION AND USER AGENT

12.1. OVERVIEW

The OpenShift Container Platform master includes a built-in OAuth server. Developers and administrators obtain OAuth access tokens to authenticate themselves to the API.

As an administrator, you can configure OAuth using the master configuration file to specify an identity provider. This can be done during an advanced installation or configured after installation.

If you installed OpenShift Container Platform using the Quick Installation or Advanced Installation method, the Deny All identity provider is used by default, which denies access for all user names and passwords. To allow access, you must choose a different identity provider and configure the master configuration file appropriately (located at /etc/origin/master/master-config.yaml by default).

When running a master without a configuration file, the Allow All identity provider is used by default, which allows any non-empty user name and password to log in. This is useful for testing purposes. To use other identity providers, or to modify any token, grant, or session options, you must run the master from a configuration file.

NOTE

Roles need to be assigned to administer the setup with an external user.

NOTE

After making changes to an identity provider you must restart the master service for the changes to take effect:

systemctl restart atomic-openshift-master

12.2. CONFIGURING IDENTITY PROVIDERS WITH ANSIBLE

For initial advanced installations, the Deny All identity provider is configured by default, though it can be overridden during installation using the **openshift_master_identity_providers** parameter, which is configurable in the inventory file. Session options in the OAuth configuration are also configurable in the inventory file.

Example 12.1. Example Identity Provider Configuration with Ansible

```
# htpasswd auth
openshift_master_identity_providers=[{'name': 'htpasswd_auth', 'login':
'true', 'challenge': 'true', 'kind': 'HTPasswdPasswordIdentityProvider',
'filename': '/etc/origin/master/htpasswd'}]
# Defining htpasswd users
#openshift_master_htpasswd_users={'user1': '<pre-hashed password>',
'user2': '<pre-hashed password>'
# or
#openshift_master_htpasswd_file=<path to local pre-generated htpasswd
file>
```

```
# Allow all auth
#openshift_master_identity_providers=[{'name': 'allow_all', 'login':
'true', 'challenge': 'true', 'kind':
'AllowAllPasswordIdentityProvider'}]
# LDAP auth
#openshift_master_identity_providers=[{'name': 'my_ldap_provider',
'challenge': 'true', 'login': 'true', 'kind':
'LDAPPasswordIdentityProvider', 'attributes': {'id': ['dn'], 'email':
['mail'], 'name': ['cn'], 'preferredUsername': ['uid']}, 'bindDN': '',
'bindPassword': '', 'ca': '', 'insecure': 'false', 'url':
'ldap://ldap.example.com:389/ou=users,dc=example,dc=com?uid'}]
# Configuring the ldap ca certificate
#openshift_master_ldap_ca=<ca text>
# or
#openshift_master_ldap_ca_file=<path to local ca file to use>
# Available variables for configuring certificates for other identity
providers:
#openshift_master_openid_ca
#openshift_master_openid_ca_file
#openshift_master_request_header_ca
#openshift_master_request_header_ca_file
```

12.3. IDENTITY PROVIDERS

You can configure the master host for authentication using your desired identity provider by modifying the master configuration file. The following sections detail the identity providers supported by OpenShift Container Platform.

There are four parameters common to all identity providers:

Parameter	Description
name	The provider name is prefixed to provider user names to form an identity name.
challenge	When true , unauthenticated token requests from non-web clients (like the CLI) are sent a WWW-Authenticate challenge header. Not supported by all identity providers.
	To prevent cross-site request forgery (CSRF) attacks against browser clients Basic authentication challenges are only sent if a X-CSRF-Token header is present on the request. Clients that expect to receive Basic WWW-Authenticate challenges should set this header to a non-empty value.

Parameter	Description
login	When true , unauthenticated token requests from web clients (like the web console) are redirected to a login page backed by this provider. Not supported by all identity providers.
	If you want users to be sent to a branded page before being redirected to the identity provider's login, then set oauthConfig \rightarrow alwaysShowProviderSelection: true in the master configuration file. This provider selection page can be customized.
mappingMetho d	Defines how new identities are mapped to users when they login. See Mapping Identities to Users for more information.

NOTE

When adding or changing identity providers, you can map identities from the new provider to existing users by setting the mappingMethod parameter to add.

12.3.1. Mapping Identities to Users

Setting the mappingMethod parameter in a master configuration file determines how identities are mapped to users:

oauthConfig:
 identityProviders:
 name: htpasswd_auth
 challenge: true
 login: false
 mappingMethod: "claim"

•

When set to the default claim value, OAuth will fail if the identity is mapped to a previously-existing user name. The following table outlines the use cases for the available mappingMethod parameter values:

Parameter	Description
claim	The default value. Provisions a user with the identity's preferred user name. Fails if a user with that user name is already mapped to another identity.
1ookup	Looks up an existing identity, user identity mapping, and user, but does not automatically provision users or identities. This allows cluster administrators to set up identities and users manually, or using an external process.

Parameter	Description
generate	Provisions a user with the identity's preferred user name. If a user with the preferred user name is already mapped to an existing identity, a unique user name is generated. For example, myuser2. This method should not be used in combination with external processes that require exact matches between OpenShift Container Platform user names and identity provider user names, such as LDAP group sync.
add	Provisions a user with the identity's preferred user name. If a user with that user name already exists, the identity is mapped to the existing user, adding to any existing identity mappings for the user. Required when multiple identity providers are configured that identify the same set of users and map to the same user names.

12.3.2. Allow All

Set AllowAllPasswordIdentityProvider in the identityProviders stanza to allow any non-empty user name and password to log in. This is the default identity provider when running OpenShift Container Platform without a master configuration file.

Example 12.2. Master Configuration Using AllowAllPasswordIdentityProvider

```
oauthConfig:
...
identityProviders:
- name: my_allow_provider 1
    challenge: true 2
    login: true 3
    mappingMethod: claim 4
    provider:
        apiVersion: v1
        kind: AllowAllPasswordIdentityProvider
```

- This provider name is prefixed to provider user names to form an identity name.
- When true, unauthenticated token requests from non-web clients (like the CLI) are sent a WWW-Authenticate challenge header for this provider.
- When **true**, unauthenticated token requests from web clients (like the web console) are redirected to a login page backed by this provider.
- Controls how mappings are established between this provider's identities and user objects, as described above.

12.3.3. Deny All

Set **DenyAllPasswordIdentityProvider** in the **identityProviders** stanza to deny access for all user names and passwords.

Example 12.3. Master Configuration Using DenyAllPasswordIdentityProvider

oauthConfig:

identityProviders:

- name: my_deny_provider 1

challenge: true 2 login: true 3

mappingMethod: claim 4

provider:

apiVersion: v1

kind: DenyAllPasswordIdentityProvider

- This provider name is prefixed to provider user names to form an identity name.
- When true, unauthenticated token requests from non-web clients (like the CLI) are sent a WWW-Authenticate challenge header for this provider.
- When **true**, unauthenticated token requests from web clients (like the web console) are redirected to a login page backed by this provider.
- Controls how mappings are established between this provider's identities and user objects, as described above.

12.3.4. HTPasswd

Set HTPasswdPasswordIdentityProvider in the identityProviders stanza to validate user names and passwords against a flat file generated using htpasswd.

NOTE

The htpasswd utility is in the httpd-tools package:

yum install httpd-tools

OpenShift Container Platform supports the Bcrypt, SHA-1, and MD5 cryptographic hash functions, and MD5 is the default for htpasswd. Plaintext, encrypted text, and other hash functions are not currently supported.

The flat file is reread if its modification time changes, without requiring a server restart.

To use the htpasswd command:

• To create a flat file with a user name and hashed password, run:

```
$ htpasswd -c </path/to/users.htpasswd> <user_name>
```

Then, enter and confirm a clear-text password for the user. The command generates a hashed version of the password.

For example:

htpasswd -c users.htpasswd user1

New password: Re-type new password: Adding password for user user1

NOTE

You can include the -b option to supply the password on the command line:

\$ htpasswd -c -b <user_name> <password>

For example:

\$ htpasswd -c -b file user1 MyPassword!
Adding password for user user1

- To add or update a login to the file, run:
 - \$ htpasswd </path/to/users.htpasswd> <user_name>
- To remove a login from the file, run:

\$ htpasswd -D </path/to/users.htpasswd> <user_name>

Example 12.4. Master Configuration Using HTPasswdPasswordIdentityProvider

oauthConfig:

identityProviders:

- name: my_htpasswd_provider 1

challenge: true 2

login: true 3

mappingMethod: claim 4

provider:

apiVersion: v1

kind: HTPasswdPasswordIdentityProvider

file: /path/to/users.htpasswd 5

- This provider name is prefixed to provider user names to form an identity name.
- When true, unauthenticated token requests from non-web clients (like the CLI) are sent a WWW-Authenticate challenge header for this provider.
- When **true**, unauthenticated token requests from web clients (like the web console) are redirected to a login page backed by this provider.
- Controls how mappings are established between this provider's identities and user objects, as described above.
- File generated using htpasswd.

12.3.5. Keystone

Set **KeystonePasswordIdentityProvider** in the **identityProviders** stanza to validate user names and passwords against an OpenStack Keystone v3 server. This enables shared authentication with an OpenStack server configured to store users in an internal Keystone database.

Example 12.5. Master Configuration Using KeystonePasswordIdentityProvider

```
oauthConfig:
...
identityProviders:
- name: my_keystone_provider 1
   challenge: true 2
   login: true 3
   mappingMethod: claim 4
   provider:
      apiVersion: v1
      kind: KeystonePasswordIdentityProvider
      domainName: default 5
      url: http://keystone.example.com:5000 6
      ca: ca.pem 7
      certFile: keystone.pem 8
      keyFile: keystonekey.pem 9
```

- This provider name is prefixed to provider user names to form an identity name.
- When true, unauthenticated token requests from non-web clients (like the CLI) are sent a WWW-Authenticate challenge header for this provider.
- When **true**, unauthenticated token requests from web clients (like the web console) are redirected to a login page backed by this provider.
- Controls how mappings are established between this provider's identities and user objects, as described above.
- 5 Keystone domain name. In Keystone, usernames are domain-specific. Only a single domain is supported.
- The URL to use to connect to the Keystone server (required).
- Optional: Certificate bundle to use to validate server certificates for the configured URL.
- 8 Optional: Client certificate to present when making requests to the configured URL.
- 9 Key for the client certificate. Required if certFile is specified.

12.3.6. LDAP Authentication

Set LDAPPasswordIdentityProvider in the identityProviders stanza to validate user names and passwords against an LDAPv3 server, using simple bind authentication.

During authentication, the LDAP directory is searched for an entry that matches the provided user name. If a single unique match is found, a simple bind is attempted using the distinguished name (DN) of the entry plus the provided password.

These are the steps taken:

- 1. Generate a search filter by combining the attribute and filter in the configured url with the user-provided user name.
- 2. Search the directory using the generated filter. If the search does not return exactly one entry, deny access.
- 3. Attempt to bind to the LDAP server using the DN of the entry retrieved from the search, and the user-provided password.
- 4. If the bind is unsuccessful, deny access.
- 5. If the bind is successful, build an identity using the configured attributes as the identity, email address, display name, and preferred user name.

The configured url is an RFC 2255 URL, which specifies the LDAP host and search parameters to use. The syntax of the URL is:

ldap://host:port/basedn?attribute?scope?filter

For the above example:

URL Component	Description
ldap	For regular LDAP, use the string ldap . For secure LDAP (LDAPS), use ldaps instead.
host:port	The name and port of the LDAP server. Defaults to localhost:389 for Idap and localhost:636 for LDAPS.
basedn	The DN of the branch of the directory where all searches should start from. At the very least, this must be the top of your directory tree, but it could also specify a subtree in the directory.
attribute	The attribute to search for. Although RFC 2255 allows a comma-separated list of attributes, only the first attribute will be used, no matter how many are provided. If no attributes are provided, the default is to use uid . It is recommended to choose an attribute that will be unique across all entries in the subtree you will be using.
scope	The scope of the search. Can be either either one or sub . If the scope is not provided, the default is to use a scope of sub .
filter	A valid LDAP search filter. If not provided, defaults to (objectClass=*)

When doing searches, the attribute, filter, and provided user name are combined to create a search filter that looks like:

(&(<filter>)(<attribute>=<username>))

For example, consider a URL of:

```
ldap://ldap.example.com/o=Acme?cn?sub?(enabled=true)
```

When a client attempts to connect using a user name of **bob**, the resulting search filter will be (& (enabled=true)(cn=bob)).

If the LDAP directory requires authentication to search, specify a **bindDN** and **bindPassword** to use to perform the entry search.

Master Configuration Using LDAPPasswordIdentityProvider

```
oauthConfig:
  identityProviders:
  - name: "my_ldap_provider" 1
    challenge: true 2
    login: true 3
    mappingMethod: claim 4
    provider:
      apiVersion: v1
      kind: LDAPPasswordIdentityProvider
      attributes:
        id: 5
        - dn
        email: 6
        - mail
        name: 7
        - cn
        preferredUsername: (8)
        - uid
      bindDN: "" 9
      bindPassword: "" 10
      ca: my-ldap-ca-bundle.crt (11)
      insecure: false 12
      url: "ldap://ldap.example.com/ou=users,dc=acme,dc=com?uid" 13
```

- This provider name is prefixed to the returned user ID to form an identity name.
- When true, unauthenticated token requests from non-web clients (like the CLI) are sent a WWW-Authenticate challenge header for this provider.
- When **true**, unauthenticated token requests from web clients (like the web console) are redirected to a login page backed by this provider.
- Controls how mappings are established between this provider's identities and user objects, as described above.
- List of attributes to use as the identity. First non-empty attribute is used. At least one attribute is required. If none of the listed attribute have a value, authentication fails.
- 6 List of attributes to use as the email address. First non-empty attribute is used.

- List of attributes to use as the display name. First non-empty attribute is used.
- List of attributes to use as the preferred user name when provisioning a user for this identity. First non-empty attribute is used.
- Optional DN to use to bind during the search phase.
- Optional password to use to bind during the search phase. This value may also be provided in an environment variable, external file, or encrypted file.
- Certificate bundle to use to validate server certificates for the configured URL. If empty, system trusted roots are used. Only applies if insecure: false.
- When true, no TLS connection is made to the server. When false, ldaps:// URLs connect using TLS, and ldap:// URLs are upgraded to TLS.
- An RFC 2255 URL which specifies the LDAP host and search parameters to use, as described above.

NOTE

To whitelist users for an LDAP integration, use the **lookup** mapping method. Before a login from LDAP would be allowed, a cluster administrator must create an identity and user object for each LDAP user.

12.3.7. Basic Authentication (Remote)

Set BasicAuthPasswordIdentityProvider in the identityProviders stanza to validate user names and passwords against a remote server using a server-to-server Basic authentication request. User names and passwords are validated against a remote URL that is protected by Basic authentication and returns JSON.

A 401 response indicates failed authentication.

A non-200 status, or the presence of a non-empty "error" key, indicates an error:

A 200 status with a sub (subject) key indicates success:

```
{"sub":"userid"} 1
```

The subject must be unique to the authenticated user and must not be able to be modified.

A successful response may optionally provide additional data, such as:

• A display name using the name key. For example:

```
{"sub":"userid", "name": "User Name", ...}
```

An email address using the email key. For example:

```
{"sub":"userid", "email":"user@example.com", ...}
```

 A preferred user name using the preferred_username key. This is useful when the unique, unchangeable subject is a database key or UID, and a more human-readable name exists. This is used as a hint when provisioning the OpenShift Container Platform user for the authenticated identity. For example:

```
{"sub":"014fbff9a07c", "preferred_username":"bob", ...}
```

Example 12.6. Master Configuration Using BasicAuthPasswordIdentityProvider

```
oauthConfig:
...
identityProviders:
- name: my_remote_basic_auth_provider 1
    challenge: true 2
    login: true 3
    mappingMethod: claim 4
    provider:
        apiVersion: v1
        kind: BasicAuthPasswordIdentityProvider
        url: https://www.example.com/remote-idp 5
        ca: /path/to/ca.file 6
        certFile: /path/to/client.crt 7
        keyFile: /path/to/client.key 8
```

- This provider name is prefixed to the returned user ID to form an identity name.
- When true, unauthenticated token requests from non-web clients (like the CLI) are sent a WWW-Authenticate challenge header for this provider.
- When **true**, unauthenticated token requests from web clients (like the web console) are redirected to a login page backed by this provider.
- Controls how mappings are established between this provider's identities and user objects, as described above.
- URL accepting credentials in Basic authentication headers.
- Optional: Certificate bundle to use to validate server certificates for the configured URL.
- Optional: Client certificate to present when making requests to the configured URL.
- 8 Key for the client certificate. Required if certFile is specified.

12.3.8. Request Header

Set RequestHeaderIdentityProvider in the identityProviders stanza to identify users from request header values, such as X-Remote-User. It is typically used in combination with an authenticating proxy, which sets the request header value. This is similar to how the remote user plug-

in in OpenShift Enterprise 2 allowed administrators to provide Kerberos, LDAP, and many other forms of enterprise authentication.

For users to authenticate using this identity provider, they must access https://<master>/oauth/authorize (and subpaths) via an authenticating proxy. To accomplish this, configure the OAuth server to redirect unauthenticated requests for OAuth tokens to the proxy endpoint that proxies to https://<master>/oauth/authorize.

To redirect unauthenticated requests from clients expecting browser-based login flows:

- 1. Set the login parameter to true.
- Set the provider.loginURL parameter to the authenticating proxy URL that will authenticate interactive clients and then proxy the request to https://<master>/oauth/authorize.

To redirect unauthenticated requests from clients expecting WWW-Authenticate challenges:

- 1. Set the challenge parameter to true.
- 2. Set the **provider.challengeURL** parameter to the authenticating proxy URL that will authenticate clients expecting **WWW-Authenticate** challenges and then proxy the request to https://<master>/oauth/authorize.

The **provider**.challengeURL and **provider**.loginURL parameters can include the following tokens in the query portion of the URL:

- \${url} is replaced with the current URL, escaped to be safe in a query parameter. For example: https://www.example.com/sso-login?then=\${url}
- \${query} is replaced with the current query string, unescaped.

 For example: https://www.example.com/auth-proxy/oauth/authorize?\${query}

WARNING

If you expect unauthenticated requests to reach the OAuth server, a **clientCA** parameter MUST be set for this identity provider, so that incoming requests are checked for a valid client certificate before the request's headers are checked for a user name. Otherwise, any direct request to the OAuth server can impersonate any identity from this provider, merely by setting a request header.

Example 12.7. Master Configuration Using RequestHeaderIdentityProvider

oauthConfig:
...
identityProviders:
- name: my_request_header_provider 1
 challenge: true 2
 login: true 3

mappingMethod: claim 4 provider: apiVersion: v1 kind: RequestHeaderIdentityProvider challengeURL: "https://www.example.com/challengingproxy/oauth/authorize?\${query}" 5 loginURL: "https://www.example.com/login-proxy/oauth/authorize? \${query}" 6 clientCA: /path/to/client-ca.file 7 clientCommonNames: 8 - my-auth-proxy headers: 9 - X-Remote-User - SSO-User emailHeaders: 10 - X-Remote-User-Email nameHeaders: 111 - X-Remote-User-Display-Name preferredUsernameHeaders: 12 - X-Remote-User-Login

- This provider name is prefixed to the user name in the request header to form an identity name.
- RequestHeaderIdentityProvider can only respond to clients that request WWW-Authenticate challenges by redirecting to a configured challengeURL. The configured URL should respond with a WWW-Authenticate challenge.
- RequestHeaderIdentityProvider can only respond to clients requesting a login flow by redirecting to a configured loginURL. The configured URL should respond with a login flow.
- Controls how mappings are established between this provider's identities and user objects, as described above.
- Optional: URL to redirect unauthenticated /oauth/authorize requests to, that will authenticate browser-based clients and then proxy their request to https://<master>/oauth/authorize. The URL that proxies to https://<master>/oauth/authorize must end with /authorize (with no trailing slash), and also proxy subpaths, in order for OAuth approval flows to work properly. \${url} is replaced with the current URL, escaped to be safe in a query parameter. \${query} is replaced with the current query string.
- Optional: URL to redirect unauthenticated /oauth/authorize requests to, that will authenticate clients which expect WWW-Authenticate challenges, and then proxy them to https://<master>/oauth/authorize. \${url} is replaced with the current URL, escaped to be safe in a query parameter. \${query} is replaced with the current query string.
- Optional: PEM-encoded certificate bundle. If set, a valid client certificate must be presented and validated against the certificate authorities in the specified file before the request headers are checked for user names.
- Optional: list of common names (cn). If set, a valid client certificate with a Common Name (cn) in the specified list must be presented before the request headers are checked for user names. If empty, any Common Name is allowed. Can only be used in combination with clientCA.

- 9 Header names to check, in order, for the user identity. The first header containing a value is used as the identity. Required, case-insensitive.
- Header names to check, in order, for an email address. The first header containing a value is used as the email address. Optional, case-insensitive.
- Header names to check, in order, for a display name. The first header containing a value is used as the display name. Optional, case-insensitive.
- Header names to check, in order, for a preferred user name, if different than the immutable identity determined from the headers specified in headers. The first header containing a value is used as the preferred user name when provisioning. Optional, case-insensitive.

Example 12.8. Apache Authentication Using RequestHeaderIdentityProvider

This example configures an authentication proxy on the same host as the master. Having the proxy and master on the same host is merely a convenience and may not be suitable for your environment. For example, if you were already running a router on the master, port 443 would not be available.

It is also important to note that while this reference configuration uses Apache's **mod_auth_form**, it is by no means required and other proxies can easily be used if the following requirements are met:

- 1. Block the X-Remote-User header from client requests to prevent spoofing.
- 2. Enforce client certificate authentication in the **RequestHeaderIdentityProvider** configuration.
- 3. Require the X-Csrf-Token header be set for all authentication request using the challenge flow.
- 4. Only the /oauth/authorize endpoint and its subpaths should be proxied, and redirects should not be rewritten to allow the backend server to send the client to the correct location.
- 5. The URL that proxies to https://<master>/oauth/authorize must end with /authorize (with no trailing slash). For example:
 - https://proxy.example.com/login-proxy/authorize?... → https://<master>/oauth/authorize?...
- 6. Subpaths of the URL that proxies to https://<master>/oauth/authorize must proxy to subpaths of https://<master>/oauth/authorize. For example:
 - https://proxy.example.com/login-proxy/authorize/approve?... → https://<master>/oauth/authorize/approve?...

Installing the Prerequisites

The mod_auth_form module is shipped as part of the mod_session package that is found in the Optional channel:

yum install -y httpd mod_ssl mod_session apr-util-openssl

Generate a CA for validating requests that submit the trusted header. This CA should be used as the file name for clientCA in the master's identity provider configuration.

```
# oadm ca create-signer-cert \
    --cert='/etc/origin/master/proxyca.crt' \
    --key='/etc/origin/master/proxyca.key' \
    --name='openshift-proxy-signer@1432232228' \
    --serial='/etc/origin/master/proxyca.serial.txt'
```

NOTE

The oadm ca create-signer-cert command generates a certificate that is valid for five years. This can be altered with the --expire-days option, but for security reasons, it is recommended to not make it greater than this value.

Generate a client certificate for the proxy. This can be done using any x509 certificate tooling. For convenience, the oadm CLI can be used:

```
# oadm create-api-client-config \
    --certificate-authority='/etc/origin/master/proxyca.crt' \
    --client-dir='/etc/origin/master/proxyca.crt' \
    --signer-cert='/etc/origin/master/proxyca.crt' \
    --signer-key='/etc/origin/master/proxyca.key' \
    --signer-serial='/etc/origin/master/proxyca.serial.txt' \
    --user='system:proxy' 1

# pushd /etc/origin/master
# cp master.server.crt /etc/pki/tls/certs/localhost.crt 2
# cp master.server.key /etc/pki/tls/private/localhost.key
# cp ca.crt /etc/pki/CA/certs/ca.crt
# cat proxy/system\:proxy.crt \
    proxy/system\:proxy.key > \
    /etc/pki/tls/certs/authproxy.pem
# popd
```

- The user name can be anything, however it is useful to give it a descriptive name as it will appear in logs.
- When running the authentication proxy on a different host name than the master, it is important to generate a certificate that matches the host name instead of using the default master certificate as shown above. The value for masterPublicURL in the /etc/origin/master/master-config.yaml file must be included in the X509v3 Subject Alternative Name in the certificate that is specified for SSLCertificateFile. If a new certificate needs to be created, the oadm ca create-server-cert command can be used.

NOTE

The oadm create-api-client-config command generates a certificate that is valid for two years. This can be altered with the --expire-days option, but for security reasons, it is recommended to not make it greater than this value.

Configuring Apache

Unlike OpenShift Enterprise 2, this proxy does not need to reside on the same host as the master. It uses a client certificate to connect to the master, which is configured to trust the X-Remote-User header.

Configure Apache per the following:

```
LoadModule auth_form_module modules/mod_auth_form.so
LoadModule session module modules/mod session.so
LoadModule request_module modules/mod_request.so
# Nothing needs to be served over HTTP. This virtual host simply
redirects to
# HTTPS.
<VirtualHost *:80>
  DocumentRoot /var/www/html
  RewriteEngine
                             0n
  RewriteRule ^{(.*)} https://%{HTTP_HOST}$1 [R,L]
</VirtualHost>
<VirtualHost *:443>
  # This needs to match the certificates you generated. See the CN and
X509v3
  # Subject Alternative Name in the output of:
  # openssl x509 -text -in /etc/pki/tls/certs/localhost.crt
  ServerName www.example.com
  DocumentRoot /var/www/html
  SSLEngine on
  SSLCertificateFile /etc/pki/tls/certs/localhost.crt
  SSLCertificateKeyFile /etc/pki/tls/private/localhost.key
  SSLCACertificateFile /etc/pki/CA/certs/ca.crt
  SSLProxyEngine on
  SSLProxyCACertificateFile /etc/pki/CA/certs/ca.crt
  # It's critical to enforce client certificates on the Master.
Otherwise
  # requests could spoof the X-Remote-User header by accessing the
Master's
  # /oauth/authorize endpoint directly.
  SSLProxyMachineCertificateFile /etc/pki/tls/certs/authproxy.pem
  # Send all requests to the console
  RewriteEngine
                             Ωn
  RewriteRule
                 ^/console(.*)$
                                   https://%
{HTTP_HOST}:8443/console$1 [R,L]
  # In order to using the challenging-proxy an X-Csrf-Token must be
present.
  RewriteCond %{REQUEST_URI} ^/challenging-proxy
  RewriteCond %{HTTP:X-Csrf-Token} ^$ [NC]
  RewriteRule ^.* - [F,L]
  <Location /challenging-proxy/oauth/authorize>
    # Insert your backend server name/ip here.
    ProxyPass https://[MASTER]:8443/oauth/authorize
    AuthType basic
```

```
</Location>
  <Location /login-proxy/oauth/authorize>
    # Insert your backend server name/ip here.
    ProxyPass https://[MASTER]:8443/oauth/authorize
    # mod_auth_form providers are implemented by mod_authn_dbm,
mod_authn_file,
    # mod_authn_dbd, mod_authnz_ldap and mod_authn_socache.
    AuthFormProvider file
    AuthType form
    AuthName openshift
    ErrorDocument 401 /login.html
  </Location>
  <ProxyMatch /oauth/authorize>
    AuthUserFile /etc/origin/master/htpasswd
    AuthName openshift
    Require valid-user
    RequestHeader set X-Remote-User %{REMOTE_USER}s env=REMOTE_USER
    # For ldap:
    # AuthBasicProvider ldap
    # AuthLDAPURL "ldap://ldap.example.com:389/ou=People,dc=my-
domain, dc=com?uid?sub?(objectClass=*)"
    # It's possible to remove the mod_auth_form usage and replace it
with
    # something like mod_auth_kerb, mod_auth_gssapi or even
mod auth mellon.
    # The former would be able to support both the login and challenge
flows
    # from the Master. Mellon would likely only support the login flow.
    # For Kerberos
    # yum install mod_auth_gssapi
    # AuthType GSSAPI
    # GssapiCredStore keytab:/etc/httpd.keytab
  </ProxyMatch>
</VirtualHost>
RequestHeader unset X-Remote-User
```

Additional mod_auth_form Requirements

A sample login page is available from the openshift_extras repository. This file should be placed in the **DocumentRoot** location (/var/www/html by default).

Creating Users

At this point, you can create the users in the system Apache is using to store accounts information. In this example, file-backed authentication is used:

```
# yum -y install httpd-tools
# touch /etc/origin/master/htpasswd
# htpasswd /etc/origin/master/htpasswd <user_name>
```

Configuring the Master

The identityProviders stanza in the /etc/origin/master/master-config.yaml file must be updated as well:

```
identityProviders:
    name: requestheader
    challenge: true
    login: true
    provider:
        apiVersion: v1
        kind: RequestHeaderIdentityProvider
        challengeURL: "https://[MASTER]/challenging-proxy/oauth/authorize?

${query}"
    loginURL: "https://[MASTER]/login-proxy/oauth/authorize?${query}"
    clientCA: /etc/origin/master/proxyca.crt
    headers:
        - X-Remote-User
```

Restarting Services

Finally, restart the following services:

```
# systemctl restart httpd
# systemctl restart atomic-openshift-master
```

Verifying the Configuration

1. Test by bypassing the proxy. You should be able to request a token if you supply the correct client certificate and header:

```
# curl -L -k -H "X-Remote-User: joe" \
    --cert /etc/pki/tls/certs/authproxy.pem \
    https://[MASTER]:8443/oauth/token/request
```

2. If you do not supply the client certificate, the request should be denied:

```
# curl -L -k -H "X-Remote-User: joe" \
   https://[MASTER]:8443/oauth/token/request
```

3. This should show a redirect to the configured **challengeURL** (with additional query parameters):

```
# curl -k -v -H 'X-Csrf-Token: 1' \
    '<masterPublicURL>/oauth/authorize?client_id=openshift-
challenging-client&response_type=token'
```

4. This should show a 401 response with a WWW-Authenticate basic challenge:

```
# curl -k -v -H 'X-Csrf-Token: 1' \
```

'<redirected challengeURL from step 3 +query>'

5. This should show a redirect with an access token:

```
# curl -k -v -u <your_user>:<your_password> \
    -H 'X-Csrf-Token: 1' '<redirected_challengeURL_from_step_3
+query>'
```

12.3.9. GitHub

Set **GitHubIdentityProvider** in the **identityProviders** stanza to use **GitHub** as an identity provider, using the **OAuth** integration.

NOTE

Using GitHub as an identity provider requires users to get a token using <master>/oauth/token/request to use with command-line tools.

WARNING

Using GitHub as an identity provider allows any GitHub user to authenticate to your server. You can limit authentication to members of specific GitHub organizations with the **organizations** configuration attribute, as shown below.

Example 12.9. Master Configuration Using GitHubIdentityProvider

```
oauthConfig:
  identityProviders:
  - name: github 1
    challenge: false 2
    login: true 3
    mappingMethod: claim 4
    provider:
      apiVersion: v1
      kind: GitHubIdentityProvider
     clientID: ... 5
     clientSecret: ... 6
     organizations: 7
      - myorganization1
      - myorganization2
     teams: 8
      - myorganization1/team-a
```

- myorganization2/team-b

- This provider name is prefixed to the GitHub numeric user ID to form an identity name. It is also used to build the callback URL.
- GitHubldentityProvider cannot be used to send WWW-Authenticate challenges.
- When **true**, unauthenticated token requests from web clients (like the web console) are redirected to GitHub to log in.
- Controls how mappings are established between this provider's identities and user objects, as described above.
- The client ID of a registered GitHub OAuth application. The application must be configured with a callback URL of <master>/oauth2callback/<identityProviderName>.
- The client secret issued by GitHub. This value may also be provided in an environment variable, external file, or encrypted file.
- Optional list of organizations. If specified, only GitHub users that are members of at least one of the listed organizations will be allowed to log in. If the GitHub OAuth application configured in clientID is not owned by the organization, an organization owner must grant third-party access in order to use this option. This can be done during the first GitHub login by the organization's administrator, or from the GitHub organization settings. Cannot be used in combination with the teams field.

Optional list of teams. If specified, only GitHub users that are members of at least one of the listed teams will be allowed to log in. If the GitHub OAuth application configured in clientID is not owned by the team's organization, an organization owner must grant third-party access in order to use this option. This can be done during the first GitHub login by the organization's administrator, or from the GitHub organization settings. Cannot be used in combination with the organizations field.

12.3.10. GitLab

Set **GitLabIdentityProvider** in the **identityProviders** stanza to use **GitLab.com** or any other GitLab instance as an identity provider, using the OAuth integration. The OAuth provider feature requires GitLab version 7.7.0 or higher.

NOTE

Using GitLab as an identity provider requires users to get a token using <master>/oauth/token/request to use with command-line tools.

Example 12.10. Master Configuration Using GitLabIdentityProvider

oauthConfig:
...
identityProviders:
- name: gitlab 1
challenge: true 2
login: true 3
mappingMethod: claim 4
provider:

apiVersion: v1

kind: GitLabIdentityProvider

url: ... 5

clientID: ... 6

clientSecret: ... 7

ca: ... 8

- This provider name is prefixed to the GitLab numeric user ID to form an identity name. It is also used to build the callback URL.
- When true, unauthenticated token requests from non-web clients (like the CLI) are sent a WWW-Authenticate challenge header for this provider. This uses the Resource Owner Password Credentials grant flow to obtain an access token from GitLab.
- When **true**, unauthenticated token requests from web clients (like the web console) are redirected to GitLab to log in.
- Controls how mappings are established between this provider's identities and user objects, as described above.
- The host URL of a GitLab OAuth provider. This could either be https://gitlab.com/ or any other self hosted instance of GitLab.
- The client ID of a registered GitLab OAuth application. The application must be configured with a callback URL of <master>/oauth2callback/<identityProviderName>.
- The client secret issued by GitLab. This value may also be provided in an environment variable, external file, or encrypted file.
- 8 CA is an optional trusted certificate authority bundle to use when making requests to the GitLab instance. If empty, the default system roots are used.

12.3.11. Google

Set **GoogleIdentityProvider** in the **identityProviders** stanza to use Google as an identity provider, using Google's OpenID Connect integration.

NOTE

Using Google as an identity provider requires users to get a token using <master>/oauth/token/request to use with command-line tools.

WARNING

Using Google as an identity provider allows any Google user to authenticate to your server. You can limit authentication to members of a specific hosted domain with the hostedDomain configuration attribute, as shown below.

Example 12.11. Master Configuration Using GoogleIdentityProvider

oauthConfig:

identityProviders:

- name: google 1 challenge: false 2 login: true 3

mappingMethod: claim 4

provider:

apiVersion: v1

kind: GoogleIdentityProvider

clientID: ... 5 clientSecret: ... 6 hostedDomain: "" 7

- This provider name is prefixed to the Google numeric user ID to form an identity name. It is also used to build the redirect URL.
- GoogleIdentityProvider cannot be used to send WWW-Authenticate challenges.
- When true, unauthenticated token requests from web clients (like the web console) are redirected to Google to log in.
- Controls how mappings are established between this provider's identities and user objects, as described above.
- The client ID of a registered Google project. The project must be configured with a redirect URI 5 of <master>/oauth2callback/<identityProviderName>.
- 6 The client secret issued by Google. This value may also be provided in an environment variable, external file, or encrypted file.
- Optional hosted domain to restrict sign-in accounts to. If empty, any Google account is allowed to authenticate.

12.3.12. OpenID Connect

Set OpenIDIdentityProvider in the identityProviders stanza to integrate with an OpenID Connect identity provider using an Authorization Code Flow.

NOTE

ID Token and UserInfo decryptions are not supported.

By default, the openid scope is requested. If required, extra scopes can be specified in the extraScopes field.

Claims are read from the JWT id_token returned from the OpenID identity provider and, if specified, from the JSON returned by the **UserInfo** URL.

At least one claim must be configured to use as the user's identity. The standard identity claim is sub.

You can also indicate which claims to use as the user's preferred user name, display name, and email address. If multiple claims are specified, the first one with a non-empty value is used. The standard claims are:

sub	The user identity.
preferred _username	The preferred user name when provisioning a user.
email	Email address.
name	Display name.

NOTE

Using an OpenID Connect identity provider requires users to get a token using <master>/oauth/token/request to use with command-line tools.

Example 12.12. Standard Master Configuration Using OpenIDIdentityProvider

```
oauthConfig:
  identityProviders:
  - name: my_openid_connect 1
    challenge: true 2
    login: true 3
    mappingMethod: claim 4
    provider:
      apiVersion: v1
      kind: OpenIDIdentityProvider
     clientID: ... 5
     clientSecret: ... 6
     claims:
        id:
        - sub 7
       preferredUsername:
        - preferred_username
       name:
        - name
       email:
        - email
     urls:
        authorize: https://myidp.example.com/oauth2/authorize 8
        token: https://myidp.example.com/oauth2/token 9
```

- This provider name is prefixed to the value of the identity claim to form an identity name. It is also used to build the redirect URL.
- 2

When true, unauthenticated token requests from non-web clients (like the CLI) are sent a **WWW-Authenticate** challenge header for this provider. This requires the OpenID provider to

- When **true**, unauthenticated token requests from web clients (like the web console) are redirected to the authorize URL to log in.
- Controls how mappings are established between this provider's identities and user objects, as described above.
- The client ID of a client registered with the OpenID provider. The client must be allowed to redirect to <master>/oauth2callback/<identityProviderName>.
- The client secret. This value may also be provided in an environment variable, external file, or encrypted file.
- Use the value of the sub claim in the returned id_token as the user's identity.
- Authorization Endpoint described in the OpenID spec. Must use https.
- Token Endpoint described in the OpenID spec. Must use https.

A custom certificate bundle, extra scopes, extra authorization request parameters, and userInfo URL can also be specified:

Example 12.13. Full Master Configuration Using OpenIDIdentityProvider

```
oauthConfig:
  identityProviders:
  - name: my_openid_connect
    challenge: false
    login: true
    mappingMethod: claim
    provider:
      apiVersion: v1
      kind: OpenIDIdentityProvider
      clientID: ...
      clientSecret: ...
      ca: my-openid-ca-bundle.crt 1
      extraScopes: 2
      - email
      - profile
      extraAuthorizeParameters: 3
        include_granted_scopes: "true"
      claims:
        id: 4
        - custom_id_claim
        - sub
        preferredUsername: 5
        - preferred_username
        - email
        name: 6
        - nickname
```

- given_name
- name
email: 7
- custom_email_claim
- email
urls:
 authorize: https://myidp.example.com/oauth2/authorize
 token: https://myidp.example.com/oauth2/token
 userInfo: https://myidp.example.com/oauth2/userinfo
8

- Certificate bundle to use to validate server certificates for the configured URLs. If empty, system trusted roots are used.
- Optional list of scopes to request, in addition to the **openid** scope, during the authorization token request.
- Optional map of extra parameters to add to the authorization token request.
- List of claims to use as the identity. First non-empty claim is used. At least one claim is required. If none of the listed claims have a value, authentication fails.
- List of claims to use as the preferred user name when provisioning a user for this identity. First non-empty claim is used.
- 6 List of claims to use as the display name. First non-empty claim is used.
- List of claims to use as the email address. First non-empty claim is used.
- 8 UserInfo Endpoint described in the OpenID spec. Must use https.

12.4. TOKEN OPTIONS

The OAuth server generates two kinds of tokens:

Access tokens	Longer-lived tokens that grant access to the API.
Authorize codes	Short-lived tokens whose only use is to be exchanged for an access token.

Use the tokenConfig stanza to set token options:

Example 12.14. Master Configuration Token Options

```
oauthConfig:
    ...
    tokenConfig:
    accessTokenMaxAgeSeconds: 86400 1
    authorizeTokenMaxAgeSeconds: 300 2
```

- Set accessTokenMaxAgeSeconds to control the lifetime of access tokens. The default lifetime is 24 hours.
- Set authorizeTokenMaxAgeSeconds to control the lifetime of authorize codes. The default lifetime is five minutes.

12.5. GRANT OPTIONS

When the OAuth server receives token requests for a client to which the user has not previously granted permission, the action that the OAuth server takes is dependent on the OAuth client's grant strategy.

When the OAuth client requesting token does not provide its own grant strategy, the server-wide default strategy is used. To configure the default strategy, set the method value in the grantConfig stanza. Valid values for method are:

auto	Auto-approve the grant and retry the request.
prompt	Prompt the user to approve or deny the grant.
deny	Auto-deny the grant and return a failure error to the client.

Example 12.15. Master Configuration Grant Options

```
oauthConfig:
...
grantConfig:
method: auto
```

12.6. SESSION OPTIONS

The OAuth server uses a signed and encrypted cookie-based session during login and redirect flows.

Use the **sessionConfig** stanza to set session options:

Example 12.16. Master Configuration Session Options

```
oauthConfig:
    ...
    sessionConfig:
    sessionMaxAgeSeconds: 300 1
    sessionName: ssn 2
    sessionSecretsFile: "..." 3
```

Controls the maximum age of a session; sessions auto-expire once a token request is complete. If auto-grant is not enabled, sessions must last as long as the user is expected to take to approve or reject a client authorization request.

- Name of the cookie used to store the session.
- File name containing serialized SessionSecrets object. If empty, a random signing and encryption secret is generated at each server start.

If no sessionSecretsFile is specified, a random signing and encryption secret is generated at each start of the master server. This means that any logins in progress will have their sessions invalidated if the master is restarted. It also means that if multiple masters are configured, they will not be able to decode sessions generated by one of the other masters.

To specify the signing and encryption secret to use, specify a **sessionSecretsFile**. This allows you separate secret values from the configuration file and keep the configuration file distributable, for example for debugging purposes.

Multiple secrets can be specified in the sessionSecretsFile to enable rotation. New sessions are signed and encrypted using the first secret in the list. Existing sessions are decrypted and authenticated by each secret until one succeeds.

Example 12.17. Session Secret Configuration:

apiVersion: v1
kind: SessionSecrets
secrets: 1
- authentication: "..." 2
 encryption: "..." 3
- authentication: "..."
 encryption: "..."

- 1 List of secrets used to authenticate and encrypt cookie sessions. At least one secret must be specified. Each secret must set an authentication and encryption secret.
- 2 Signing secret, used to authenticate sessions using HMAC. Recommended to use a secret with 32 or 64 bytes.
- Encrypting secret, used to encrypt sessions. Must be 16, 24, or 32 characters long, to select AES-128, AES-192, or AES-256.

12.7. PREVENTING CLI VERSION MISMATCH WITH USER AGENT

OpenShift Container Platform implements a user agent that can be used to prevent an application developer's CLI accessing the OpenShift Container Platform API.

User agents for the OpenShift Container Platform CLI are constructed from a set of values within OpenShift Container Platform:

<command>/<version> (<platform>/<architecture>) <client>/<git_commit>

So, for example, when:

- <command> = oc
- <version> = The client version. For example, v3.3.0. Requests made against the Kubernetes API at /api receive the Kubernetes version, while requests made against the OpenShift Container Platform API at /oapi receive the OpenShift Container Platform version (as specified by oc version)
- <platform> = linux
- <architecture> = amd64
- <cli><cli>< = openshift, or kubernetes depending on if the request is made against the Kubernetes API at /api, or the OpenShift Container Platform API at /oapi
- <git_commit> = The Git commit of the client version (for example, f034127)

the user agent will be:

```
oc/v3.3.0 (linux/amd64) openshift/f034127
```

As an OpenShift Container Platform administrator, you can prevent clients from accessing the API with the userAgentMatching configuration setting of a master configuration. So, if a client is using a particular library or binary, they will be prevented from accessing the API.

The following user agent example denies the Kubernetes 1.2 client binary, OpenShift Origin 1.1.3 binary, and the POST and PUT httpVerbs:

```
policyConfig:
    userAgentMatchingConfig:
    defaultRejectionMessage: "Your client is too old. Go to
https://example.org to update it."
    deniedClients:
        - regex: '\w+/v(?:(?:1\.1\.1)|(?:1\.0\.1)) \(.+/.+\) openshift/\w{7}'
        - regex: '\w+/v(?:1\.1\.3) \(.+/.+\) openshift/\w{7}'
        httpVerbs:
        - POST
        - PUT
        - regex: '\w+/v1\.2\.0 \(.+/.+\) kubernetes/\w{7}'
        httpVerbs:
        - POST
        - POST
        - PUT
        requiredClients: null
```

Administrators can also deny clients that do not exactly match the expected clients:

```
policyConfig:
   userAgentMatchingConfig:
    defaultRejectionMessage: "Your client is too old. Go to
https://example.org to update it."
    deniedClients: []
    requiredClients:
    - regex: '\w+/v1\.1\.3 \(.+/.+\) openshift/\w{7}'
    - regex: '\w+/v1\.2\.0 \(.+/.+\) kubernetes/\w{7}'
```

httpVerbs:

- POST
- PUT

NOTE

When the client's user agent mismatches the configuration, errors occur. To ensure that mutating requests match, enforce a whitelist. Rules are mapped to specific verbs, so you can ban mutating requests while allowing non-mutating requests.

CHAPTER 13. SYNCING GROUPS WITH LDAP

13.1. OVERVIEW

As an OpenShift Container Platform administrator, you can use groups to manage users, change their permissions, and enhance collaboration. Your organization may have already created user groups and stored them in an LDAP server. OpenShift Container Platform can sync those LDAP records with internal OpenShift Container Platform records, enabling you to manage your groups in one place. OpenShift Container Platform currently supports group sync with LDAP servers using three common schemas for defining group membership: RFC 2307, Active Directory, and augmented Active Directory.

NOTE

You must have cluster-admin privileges to sync groups.

13.2. CONFIGURING LDAP SYNC

Before you can run LDAP sync, you need a sync configuration file. This file contains LDAP client configuration details:

- Configuration for connecting to your LDAP server.
- Sync configuration options that are dependent on the schema used in your LDAP server.

A sync configuration file can also contain an administrator-defined list of name mappings that maps OpenShift Container Platform Group names to groups in your LDAP server.

13.2.1. LDAP Client Configuration

Example 13.1. LDAP Client Configuration

url: ldap://10.0.0.0:389 1

bindDN: cn=admin, dc=example, dc=com 2

bindPassword: password 3

insecure: false 4

ca: my-ldap-ca-bundle.crt 5

- The connection protocol, IP address of the LDAP server hosting your database, and the port to connect to, formatted as scheme://host:port.
- Optional distinguished name (DN) to use as the Bind DN. OpenShift Container Platform uses this if elevated privilege is required to retrieve entries for the sync operation.
- Optional password to use to bind. OpenShift Container Platform uses this if elevated privilege is necessary to retrieve entries for the sync operation. This value may also be provided in an environment variable, external file, or encrypted file.
- When true, no TLS connection is made to the server. When false, secure LDAP (ldaps://) URLs connect using TLS, and insecure LDAP (ldap://) URLs are upgraded to TLS.

5

The certificate bundle to use for validating server certificates for the configured URL. If empty, OpenShift Container Platform uses system-trusted roots. This only applies if insecure is set

13.2.2. LDAP Query Definition

Sync configurations consist of LDAP query definitions for the entries that are required for synchronization. The specific definition of an LDAP query depends on the schema used to store membership information in the LDAP server.

Example 13.2. LDAP Query Definition

baseDN: ou=users, dc=example, dc=com 1

scope: sub 2

derefAliases: never 3

timeout: 0 4

filter: (objectClass=inetOrgPerson) 5

pageSize: 0 6

- The distinguished name (DN) of the branch of the directory where all searches will start from. It is required that you specify the top of your directory tree, but you can also specify a subtree in the directory.
- The scope of the search. Valid values are base, one, or sub. If this is left undefined, then a scope of sub is assumed. Descriptions of the scope options can be found in the table below.
- The behavior of the search with respect to aliases in the LDAP tree. Valid values are never, search, base, or always. If this is left undefined, then the default is to always dereference aliases. Descriptions of the dereferencing behaviors can be found in the table below.
- The time limit allowed for the search by the client, in seconds. A value of 0 imposes no client-side limit.
- A valid LDAP search filter. If this is left undefined, then the default is (objectClass=*).
- The optional maximum size of response pages from the server, measured in LDAP entries. If set to 0, no size restrictions will be made on pages of responses. Setting paging sizes is necessary when queries return more entries than the client or server allow by default.

Table 13.1. LDAP Search Scope Options

LDAP Search Scope	Description
base	Only consider the object specified by the base DN given for the query.
one	Consider all of the objects on the same level in the tree as the base DN for the query.
sub	Consider the entire subtree rooted at the base DN given for the query.

Table 13.2. LDAP Dereferencing Behaviors

Dereferencing Behavior	Description
never	Never dereference any aliases found in the LDAP tree.
search	Only dereference aliases found while searching.
base	Only dereference aliases while finding the base object.
always	Always dereference all aliases found in the LDAP tree.

13.2.3. User-Defined Name Mapping

A user-defined name mapping explicitly maps the names of OpenShift Container Platform Groups to unique identifiers that find groups on your LDAP server. The mapping uses normal YAML syntax. A user-defined mapping can contain an entry for every group in your LDAP server or only a subset of those groups. If there are groups on the LDAP server that do not have a user-defined name mapping, the default behavior during sync is to use the attribute specified as the Group's name.

Example 13.3. User-Defined Name Mapping

```
groupUIDNameMapping:
```

```
"cn=group1,ou=groups,dc=example,dc=com": firstgroup
"cn=group2,ou=groups,dc=example,dc=com": secondgroup
```

"cn=group3,ou=groups,dc=example,dc=com": thirdgroup

13.3. RUNNING LDAP SYNC

Once you have created a sync configuration file, then sync can begin. OpenShift Container Platform allows administrators to perform a number of different sync types with the same server.

NOTE

By default, all group synchronization or pruning operations are dry-run, so you must set the --confirm flag on the sync-groups command in order to make changes to OpenShift Container Platform Group records.

To sync all groups from the LDAP server with OpenShift Container Platform:

```
$ oadm groups sync --sync-config=config.yaml --confirm
```

To sync all Groups already in OpenShift Container Platform that correspond to groups in the LDAP server specified in the configuration file:

```
$ oadm groups sync --type=openshift --sync-config=config.yaml --confirm
```

To sync a subset of LDAP groups with OpenShift Container Platform, you can use whitelist files, blacklist files, or both:

NOTE

Any combination of blacklist files, whitelist files, or whitelist literals will work; whitelist literals can be included directly in the command itself. This applies to groups found on LDAP servers, as well as Groups already present in OpenShift Container Platform. Your files must contain one unique group identifier per line.

```
$ oadm groups sync --whitelist=<whitelist_file> \
                   --sync-config=config.yaml
                   --confirm
$ oadm groups sync --blacklist=<blacklist_file> \
                   --sync-config=config.yaml
                   --confirm
$ oadm groups sync <group_unique_identifier>
                   --sync-config=config.yaml
                   --confirm
$ oadm groups sync <group_unique_identifier>
                   --whitelist=<whitelist_file> \
                   --blacklist=<blacklist_file>
                   --sync-config=config.yaml
                   --confirm
$ oadm groups sync --type=openshift
                   --whitelist=<whitelist_file>
                   --sync-config=config.yaml
                   --confirm
```

13.4. RUNNING A GROUP PRUNING JOB

An administrator can also choose to remove groups from OpenShift Container Platform records if the records on the LDAP server that created them are no longer present. The prune job will accept the same sync configuration file and white- or black-lists as used for the sync job.

For example, if groups had previously been synchronized from LDAP using some *config.yaml* file, and some of those groups no longer existed on the LDAP server, the following command would determine which Groups in OpenShift Container Platform corresponded to the deleted groups in LDAP and then remove them from OpenShift Container Platform:

```
$ oadm groups prune --sync-config=config.yaml --confirm
```

13.5. SYNC EXAMPLES

This section contains examples for the RFC 2307, Active Directory, and augmented Active Directory schemas. All of the following examples synchronize a group named admins that has two members: Jane and Jim. Each example explains:

- How the group and users are added to the LDAP server.
- What the LDAP sync configuration file looks like.

• What the resulting Group record in OpenShift Container Platform will be after synchronization.

NOTE

These examples assume that all users are direct members of their respective groups. Specifically, no groups have other groups as members. See Nested Membership Sync Example for information on how to sync nested groups.

13.5.1. RFC 2307

In the RFC 2307 schema, both users (Jane and Jim) and groups exist on the LDAP server as first-class entries, and group membership is stored in attributes on the group. The following snippet of **ldif** defines the users and group for this schema:

Example 13.4. LDAP Entries Using RFC 2307 Schema: rfc2307.ldif

```
dn: ou=users,dc=example,dc=com
objectClass: organizationalUnit
ou: users
dn: cn=Jane, ou=users, dc=example, dc=com
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
cn: Jane
sn: Smith
displayName: Jane Smith
mail: jane.smith@example.com
dn: cn=Jim, ou=users, dc=example, dc=com
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
cn: Jim
sn: Adams
displayName: Jim Adams
mail: jim.adams@example.com
dn: ou=groups, dc=example, dc=com
objectClass: organizationalUnit
ou: groups
dn: cn=admins, ou=groups, dc=example, dc=com 1
objectClass: groupOfNames
cn: admins
owner: cn=admin, dc=example, dc=com
description: System Administrators
member: cn=Jane, ou=users, dc=example, dc=com (2)
member: cn=Jim, ou=users, dc=example, dc=com
```

- 1 The group is a first-class entry in the LDAP server.
- Members of a group are listed with an identifying reference as attributes on the group.

To sync this group, you must first create the configuration file. The RFC 2307 schema requires you to provide an LDAP query definition for both user and group entries, as well as the attributes with which to represent them in the internal OpenShift Container Platform records.

For clarity, the Group you create in OpenShift Container Platform should use attributes other than the distinguished name whenever possible for user- or administrator-facing fields. For example, identify the users of a Group by their e-mail, and use the name of the group as the common name. The following configuration file creates these relationships:

NOTE

If using user-defined name mappings, your configuration file will differ.

Example 13.5. LDAP Sync Configuration Using RFC 2307 Schema: rfc2307_config.yaml

```
kind: LDAPSyncConfig
apiVersion: v1
url: ldap://LDAP_SERVICE_IP:389 1
insecure: false 2
rfc2307:
    groupsQuery:
        baseDN: "ou=groups, dc=example, dc=com"
        scope: sub
        derefAliases: never
        pageSize: 0
    groupUIDAttribute: dn 3
    groupNameAttributes: [ cn ] 4
    groupMembershipAttributes: [ member ] 5
    usersQuery:
        baseDN: "ou=users, dc=example, dc=com"
        scope: sub
        derefAliases: never
        pageSize: 0
    userUIDAttribute: dn 6
    userNameAttributes: [ mail ] 7
    tolerateMemberNotFoundErrors: false
    tolerateMemberOutOfScopeErrors: false
```

- The IP address and host of the LDAP server where this group's record is stored.
- When true, no TLS connection is made to the server. When false, secure LDAP (ldaps://) URLs connect using TLS, and insecure LDAP (ldap://) URLs are upgraded to TLS.
- The attribute that uniquely identifies a group on the LDAP server. You cannot specify groupsQuery filters when using DN for groupUIDAttribute. For fine-grained filtering, use the whitelist / blacklist method.
- The attribute to use as the name of the Group.
- 5 The attribute on the group that stores the membership information.
- 6

The attribute that uniquely identifies a user on the LDAP server. You cannot specify usersQuery filters when using DN for userUIDAttribute. For fine-grained filtering, use the

The attribute to use as the name of the user in the OpenShift Container Platform Group record.

To run sync with the rfc2307_config.yaml file:

```
$ oadm groups sync --sync-config=rfc2307_config.yaml --confirm
```

OpenShift Container Platform creates the following Group record as a result of the above sync operation:

Example 13.6. OpenShift Container Platform Group Created Using rfc2307_config.yaml

- The last time this Group was synchronized with the LDAP server, in ISO 6801 format.
- The unique identifier for the group on the LDAP server.
- 3 The IP address and host of the LDAP server where this Group's record is stored.
- The name of the Group as specified by the sync file.
- The users that are members of the Group, named as specified by the sync file.

13.5.1.1. RFC2307 with User-Defined Name Mappings

When syncing groups with user-defined name mappings, the configuration file changes to contain these mappings as shown below.

Example 13.7. LDAP Sync Configuration Using RFC 2307 Schema With User-Defined Name Mappings: rfc2307_config_user_defined.yaml

```
kind: LDAPSyncConfig
apiVersion: v1
groupUIDNameMapping:
   "cn=admins,ou=groups,dc=example,dc=com": Administrators 1
```

```
rfc2307:
    groupsQuery:
        baseDN: "ou=groups, dc=example, dc=com"
        scope: sub
        derefAliases: never
        pageSize: 0
    groupUIDAttribute: dn 2
    groupNameAttributes: [ cn ] 3
    groupMembershipAttributes: [ member ]
    usersQuery:
        baseDN: "ou=users, dc=example, dc=com"
        scope: sub
        derefAliases: never
        pageSize: 0
    userUIDAttribute: dn 4
    userNameAttributes: [ mail ]
    tolerateMemberNotFoundErrors: false
    tolerateMemberOutOfScopeErrors: false
```

- The user-defined name mapping.
- The unique identifier attribute that is used for the keys in the user-defined name mapping. You cannot specify **groupsQuery** filters when using DN for groupUIDAttribute. For fine-grained filtering, use the whitelist / blacklist method.
- The attribute to name OpenShift Container Platform Groups with if their unique identifier is not in the user-defined name mapping.
- The attribute that uniquely identifies a user on the LDAP server. You cannot specify usersQuery filters when using DN for userUIDAttribute. For fine-grained filtering, use the whitelist / blacklist method.

To run sync with the rfc2307_config_user_defined.yaml file:

```
$ oadm groups sync --sync-config=rfc2307_config_user_defined.yaml --
confirm
```

OpenShift Container Platform creates the following Group record as a result of the above sync operation:

Example 13.8. OpenShift Container Platform Group Created Using rfc2307 config user defined.yaml

```
apiVersion: v1
kind: Group
metadata:
  annotations:
    openshift.io/ldap.sync-time: 2015-10-13T10:08:38-0400
    openshift.io/ldap.uid: cn=admins,ou=groups,dc=example,dc=com
    openshift.io/ldap.url: LDAP_SERVER_IP:389
    creationTimestamp:
    name: Administrators 1
```

users:

- jane.smith@example.com
- jim.adams@example.com

The name of the Group as specified by the user-defined name mapping.

13.5.2. RFC 2307 with User-Defined Error Tolerances

By default, if the groups being synced contain members whose entries are outside of the scope defined in the member query, the group sync fails with an error:

Error determining LDAP group membership for "<group>": membership lookup for user "<user>" in group "<group>" failed because of "search for entry with dn="<user-dn>" would search outside of the base dn specified (dn=" <base-dn>")".

This often indicates a mis-configured baseDN in the usersQuery field. However, in cases where the baseDN intentionally does not contain some of the members of the group, setting tolerateMemberOutOfScopeErrors: true allows the group sync to continue. Out of scope members will be ignored.

Similarly, when the group sync process fails to locate a member for a group, it fails outright with errors:

Error determining LDAP group membership for "<group>": membership lookup for user "<user>" in group "<group>" failed because of "search for entry with base dn="<user-dn>" refers to a non-existent entry".

Error determining LDAP group membership for "<group>": membership lookup for user "<user>" in group "<group>" failed because of "search for entry with base dn="<user-dn>" and filter "<filter>" did not return any results".

This often indicates a mis-configured usersQuery field. However, in cases where the group contains member entries that are known to be missing, setting tolerateMemberNotFoundErrors: true allows the group sync to continue. Problematic members will be ignored.

WARNING

Enabling error tolerances for the LDAP group sync causes the sync process to ignore problematic member entries. If the LDAP group sync is not configured correctly, this could result in synced OpenShift Container Platform groups missing members.

Example 13.9. LDAP Entries Using RFC 2307 Schema With Problematic Group Membership: rfc2307 problematic users.ldif

dn: ou=users,dc=example,dc=com
objectClass: organizationalUnit

```
ou: users
dn: cn=Jane,ou=users,dc=example,dc=com
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
cn: Jane
sn: Smith
displayName: Jane Smith
mail: jane.smith@example.com
dn: cn=Jim, ou=users, dc=example, dc=com
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
cn: Jim
sn: Adams
displayName: Jim Adams
mail: jim.adams@example.com
dn: ou=groups, dc=example, dc=com
objectClass: organizationalUnit
ou: groups
dn: cn=admins,ou=groups,dc=example,dc=com
objectClass: groupOfNames
cn: admins
owner: cn=admin, dc=example, dc=com
description: System Administrators
member: cn=Jane, ou=users, dc=example, dc=com
member: cn=Jim, ou=users, dc=example, dc=com
member: cn=INVALID, ou=users, dc=example, dc=com 1
member: cn=Jim,ou=OUTOFSCOPE,dc=example,dc=com 2
```

- A member that does not exist on the LDAP server.
- A member that may exist, but is not under the baseDN in the user query for the sync job.

In order to tolerate the errors in the above example, the following additions to your sync configuration file must be made:

Example 13.10. LDAP Sync Configuration Using RFC 2307 Schema Tolerating Errors: rfc2307_config_tolerating.yaml

```
kind: LDAPSyncConfig
apiVersion: v1
url: ldap://LDAP_SERVICE_IP:389
rfc2307:
    groupsQuery:
        baseDN: "ou=groups,dc=example,dc=com"
        scope: sub
        derefAliases: never
    groupUIDAttribute: dn
```

```
groupNameAttributes: [ cn ]
groupMembershipAttributes: [ member ]
usersQuery:
    baseDN: "ou=users, dc=example, dc=com"
    scope: sub
    derefAliases: never
userUIDAttribute: dn 1
userNameAttributes: [ mail ]
tolerateMemberNotFoundErrors: true 2
tolerateMemberOutOfScopeErrors: true 3
```

- When true, the sync job tolerates groups for which some members were not found, and members whose LDAP entries are not found are ignored. The default behavior for the sync job is to fail if a member of a group is not found.
- When true, the sync job tolerates groups for which some members are outside the user scope given in the usersQuery base DN, and members outside the member query scope are ignored. The default behavior for the sync job is to fail if a member of a group is out of scope.
- The attribute that uniquely identifies a user on the LDAP server. You cannot specify usersQuery filters when using DN for userUIDAttribute. For fine-grained filtering, use the whitelist / blacklist method.

To run sync with the *rfc2307_config_tolerating.yaml* file:

```
$ oadm groups sync --sync-config=rfc2307_config_tolerating.yaml --confirm
```

OpenShift Container Platform creates the following group record as a result of the above sync operation:

Example 13.11. OpenShift Container Platform Group Created Using rfc2307_config.yaml

```
apiVersion: v1
kind: Group
metadata:
   annotations:
     openshift.io/ldap.sync-time: 2015-10-13T10:08:38-0400
     openshift.io/ldap.uid: cn=admins, ou=groups, dc=example, dc=com
     openshift.io/ldap.url: LDAP_SERVER_IP:389
     creationTimestamp:
     name: admins
users: 1
     - jane.smith@example.com
     - jim.adams@example.com
```

The users that are members of the group, as specified by the sync file. Members for which lookup encountered tolerated errors are absent.

13.5.3. Active Directory

In the Active Directory schema, both users (Jane and Jim) exist in the LDAP server as first-class entries, and group membership is stored in attributes on the user. The following snippet of **ldif** defines the users and group for this schema:

Example 13.12. LDAP Entries Using Active Directory Schema: active_directory.ldif

dn: ou=users, dc=example, dc=com objectClass: organizationalUnit ou: users dn: cn=Jane, ou=users, dc=example, dc=com objectClass: person objectClass: organizationalPerson objectClass: inetOrgPerson objectClass: testPerson cn: Jane sn: Smith displayName: Jane Smith mail: jane.smith@example.com memberOf: admins 1 dn: cn=Jim, ou=users, dc=example, dc=com objectClass: person objectClass: organizationalPerson objectClass: inetOrgPerson objectClass: testPerson cn: Jim sn: Adams displayName: Jim Adams mail: jim.adams@example.com memberOf: admins

1

The user's group memberships are listed as attributes on the user, and the group does not exist as an entry on the server. The memberOf attribute does not have to be a literal attribute on the user; in some LDAP servers, it is created during search and returned to the client, but not committed to the database.

To sync this group, you must first create the configuration file. The Active Directory schema requires you to provide an LDAP query definition for user entries, as well as the attributes to represent them with in the internal OpenShift Container Platform Group records.

For clarity, the Group you create in OpenShift Container Platform should use attributes other than the distinguished name whenever possible for user- or administrator-facing fields. For example, identify the users of a Group by their e-mail, but define the name of the Group by the name of the group on the LDAP server. The following configuration file creates these relationships:

Example 13.13. LDAP Sync Configuration Using Active Directory Schema: active_directory_config.yaml

kind: LDAPSyncConfig
apiVersion: v1
url: ldap://LDAP_SERVICE_IP:389
activeDirectory:

```
usersQuery:
    baseDN: "ou=users,dc=example,dc=com"
    scope: sub
    derefAliases: never
    filter: (objectclass=inetOrgPerson)
    pageSize: 0
userNameAttributes: [ mail ] 1
groupMembershipAttributes: [ memberOf ] 2
```

- The attribute to use as the name of the user in the OpenShift Container Platform Group record.
- The attribute on the user that stores the membership information.

To run sync with the active_directory_config.yaml file:

```
$ oadm groups sync --sync-config=active_directory_config.yaml --confirm
```

OpenShift Container Platform creates the following Group record as a result of the above sync operation:

Example 13.14. OpenShift Container Platform Group Created Using active_directory_config.yaml

```
apiVersion: v1
kind: Group
metadata:
   annotations:
     openshift.io/ldap.sync-time: 2015-10-13T10:08:38-0400 1
     openshift.io/ldap.uid: admins 2
     openshift.io/ldap.url: LDAP_SERVER_IP:389 3
     creationTimestamp:
     name: admins 4
users: 5
- jane.smith@example.com
- jim.adams@example.com
```

- The last time this Group was synchronized with the LDAP server, in ISO 6801 format.
- The unique identifier for the group on the LDAP server.
- 3 The IP address and host of the LDAP server where this Group's record is stored.
- 4 The name of the group as listed in the LDAP server.
- 5 The users that are members of the Group, named as specified by the sync file.

13.5.4. Augmented Active Directory

In the augmented Active Directory schema, both users (Jane and Jim) and groups exist in the LDAP server as first-class entries, and group membership is stored in attributes on the user. The following snippet of **ldif** defines the users and group for this schema:

Example 13.15. LDAP Entries Using Augmented Active Directory Schema: augmented_active_directory.ldif

```
dn: ou=users, dc=example, dc=com
objectClass: organizationalUnit
ou: users
dn: cn=Jane, ou=users, dc=example, dc=com
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: testPerson
cn: Jane
sn: Smith
displayName: Jane Smith
mail: jane.smith@example.com
memberOf: cn=admins,ou=groups,dc=example,dc=com 1
dn: cn=Jim, ou=users, dc=example, dc=com
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: testPerson
cn: Jim
sn: Adams
displayName: Jim Adams
mail: jim.adams@example.com
memberOf: cn=admins,ou=groups,dc=example,dc=com
dn: ou=groups,dc=example,dc=com
objectClass: organizationalUnit
ou: groups
dn: cn=admins,ou=groups,dc=example,dc=com 2
objectClass: groupOfNames
cn: admins
owner: cn=admin, dc=example, dc=com
description: System Administrators
member: cn=Jane, ou=users, dc=example, dc=com
member: cn=Jim, ou=users, dc=example, dc=com
```

- The user's group memberships are listed as attributes on the user.
- 2 The group is a first-class entry on the LDAP server.

To sync this group, you must first create the configuration file. The augmented Active Directory schema requires you to provide an LDAP query definition for both user entries and group entries, as well as the attributes with which to represent them in the internal OpenShift Container Platform Group records.

For clarity, the Group you create in OpenShift Container Platform should use attributes other than the distinguished name whenever possible for user- or administrator-facing fields. For example, identify the users of a Group by their e-mail, and use the name of the Group as the common name. The following configuration file creates these relationships.

Example 13.16. LDAP Sync Configuration Using Augmented Active Directory Schema: augmented_active_directory_config.yaml

```
kind: LDAPSyncConfig
apiVersion: v1
url: ldap://LDAP_SERVICE_IP:389
augmentedActiveDirectory:
    groupsQuery:
        baseDN: "ou=groups, dc=example, dc=com"
        scope: sub
        derefAliases: never
        pageSize: 0
    groupUIDAttribute: dn 1
    groupNameAttributes: [ cn ] 2
    usersQuery:
        baseDN: "ou=users, dc=example, dc=com"
        scope: sub
        derefAliases: never
        pageSize: 0
    userNameAttributes: [ mail ] 3
    groupMembershipAttributes: [ memberOf ] 4
```

- The attribute that uniquely identifies a group on the LDAP server. You cannot specify groupsQuery filters when using DN for groupUIDAttribute. For fine-grained filtering, use the whitelist / blacklist method.
- The attribute to use as the name of the Group.
- The attribute to use as the name of the user in the OpenShift Container Platform Group record.
- The attribute on the user that stores the membership information.

To run sync with the augmented_active_directory_config.yaml file:

```
$ oadm groups sync --sync-config=augmented_active_directory_config.yaml --
confirm
```

OpenShift Container Platform creates the following Group record as a result of the above sync operation:

Example 13.17. OpenShift Group Created Using augmented_active_directory_config.yaml

```
apiVersion: v1
kind: Group
metadata:
   annotations:
```

users: 5

- jane.smith@example.com
- jim.adams@example.com
- The last time this Group was synchronized with the LDAP server, in ISO 6801 format.
- The unique identifier for the group on the LDAP server.
- The IP address and host of the LDAP server where this Group's record is stored.
- The name of the Group as specified by the sync file.
- The users that are members of the Group, named as specified by the sync file.

13.6. NESTED MEMBERSHIP SYNC EXAMPLE

Groups in OpenShift Container Platform do not nest. The LDAP server must flatten group membership before the data can be consumed. Microsoft's Active Directory Server supports this feature via the LDAP_MATCHING_RULE_IN_CHAIN rule, which has the OID 1.2.840.113556.1.4.1941. Furthermore, only explicitly whitelisted groups can be synced when using this matching rule.

This section has an example for the augmented Active Directory schema, which synchronizes a group named admins that has one user Jane and one group otheradmins as members. The otheradmins group has one user member: Jim. This example explains:

- How the group and users are added to the LDAP server.
- What the LDAP sync configuration file looks like.
- What the resulting Group record in OpenShift Container Platform will be after synchronization.

In the augmented Active Directory schema, both users (Jane and Jim) and groups exist in the LDAP server as first-class entries, and group membership is stored in attributes on the user or the group. The following snippet of ldif defines the users and groups for this schema:

LDAP Entries Using Augmented Active Directory Schema With Nested Members: augmented_active_directory_nested.ldif

```
dn: ou=users,dc=example,dc=com
objectClass: organizationalUnit
ou: users

dn: cn=Jane,ou=users,dc=example,dc=com
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: testPerson
```

cn: Jane sn: Smith displayName: Jane Smith mail: jane.smith@example.com memberOf: cn=admins,ou=groups,dc=example,dc=com 1 dn: cn=Jim, ou=users, dc=example, dc=com objectClass: person objectClass: organizationalPerson objectClass: inetOrgPerson objectClass: testPerson cn: Jim sn: Adams displayName: Jim Adams mail: jim.adams@example.com memberOf: cn=otheradmins,ou=groups,dc=example,dc=com 2 dn: ou=groups,dc=example,dc=com objectClass: organizationalUnit ou: groups dn: cn=admins,ou=groups,dc=example,dc=com 3 objectClass: group cn: admins owner: cn=admin, dc=example, dc=com description: System Administrators member: cn=Jane, ou=users, dc=example, dc=com member: cn=otheradmins,ou=groups,dc=example,dc=com dn: cn=otheradmins, ou=groups, dc=example, dc=com 4 objectClass: group cn: otheradmins owner: cn=admin, dc=example, dc=com description: Other System Administrators memberOf: cn=admins,ou=groups,dc=example,dc=com 5 6

- 1 2 5 The user's and group's memberships are listed as attributes on the object.
- The groups are first-class entries on the LDAP server.

member: cn=Jim, ou=users, dc=example, dc=com

6 The otheradmins group is a member of the admins group.

To sync nested groups with Active Directory, you must provide an LDAP query definition for both user entries and group entries, as well as the attributes with which to represent them in the internal OpenShift Container Platform Group records. Furthermore, certain changes are required in this configuration:

- The oadm groups sync command must explicitly whitelist groups.
- The user's groupMembershipAttributes must include "memberOf:1.2.840.113556.1.4.1941:" to comply with the LDAP_MATCHING_RULE_IN_CHAIN rule.
- The groupUIDAttribute must be set to dn.

- The groupsQuery:
 - Must not set filter.
 - Must set a valid derefAliases.
 - Should not set baseDN as that value is ignored.
 - Should not set scope as that value is ignored.

For clarity, the Group you create in OpenShift Container Platform should use attributes other than the distinguished name whenever possible for user- or administrator-facing fields. For example, identify the users of a Group by their e-mail, and use the name of the Group as the common name. The following configuration file creates these relationships:

LDAP Sync Configuration Using Augmented Active Directory Schema With Nested Members: augmented_active_directory_config_nested.yaml

```
kind: LDAPSyncConfig
apiVersion: v1
url: ldap://LDAP_SERVICE_IP:389
augmentedActiveDirectory:
    groupsQuery: 1
        derefAliases: never
        pageSize: 0
    groupUIDAttribute: dn 2
    groupNameAttributes: [ cn ] 3
    usersQuery:
        baseDN: "ou=users, dc=example, dc=com"
        scope: sub
        derefAliases: never
        filter: (objectclass=inetOrgPerson)
        pageSize: 0
    userNameAttributes: [ mail ] 4
    groupMembershipAttributes: [ "member0f:1.2.840.113556.1.4.1941:" ] 5
```

- groupsQuery filters cannot be specified. The groupsQuery base DN and scope values are ignored, groupsQuery must set a valid derefAliases.
- The attribute that uniquely identifies a group on the LDAP server. It must be set to dn.
- The attribute to use as the name of the Group.
- The attribute to use as the name of the user in the OpenShift Container Platform Group record. mailor sAMAccountName are preferred choices in most installations.
- The attribute on the user that stores the membership information. Note the use of LDAP MATCHING RULE IN CHAIN.

To run sync with the **augmented_active_directory_config_nested.yaml** file:

```
$ oadm groups sync \
   'cn=admins,ou=groups,dc=example,dc=com' \
```

```
--sync-config=augmented_active_directory_config_nested.yaml \
--confirm
```

NOTE

You must explicitly whitelist the cn=admins, ou=groups, dc=example, dc=com group.

OpenShift Container Platform creates the following Group record as a result of the above sync operation:

OpenShift Group Created Using augmented_active_directory_config_nested.yaml

- The last time this Group was synchronized with the LDAP server, in ISO 6801 format.
- The unique identifier for the group on the LDAP server.
- 3 The IP address and host of the LDAP server where this Group's record is stored.
- The name of the Group as specified by the sync file.
- The users that are members of the Group, named as specified by the sync file. Note that members of nested groups are included since the group membership was flattened by the Microsoft Active Directory Server.

13.7. LDAP SYNC CONFIGURATION SPECIFICATION

The object specification for the configuration file is below. Note that the different schema objects have different fields. For example, v1.ActiveDirectoryConfig has no groupsQuery field whereas v1.RFC2307Config and v1.AugmentedActiveDirectoryConfig both do.

13.7.1. v1.LDAPSyncConfig

LDAPSyncConfig holds the necessary configuration options to define an LDAP group sync.

Name	Description	Schema

Name	Description	Schema
kind	String value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: http://releases.k8s.io/HEAD/docs/devel/api-conventions.md#types-kinds	string
apiVersion	Defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: http://releases.k8s.io/HEAD/docs/devel/api-conventions.md#resources	string
url	Host is the scheme, host and port of the LDAP server to connect to: scheme://host:port	string
bindDN	Optional DN to bind to the LDAP server with.	string
bindPassword	Optional password to bind with during the search phase.	v1.StringSource
insecure	If true, indicates the connection should not use TLS. Cannot be set to true with a URL scheme of ldaps://Iffalse, ldaps://URLs connect using TLS, and ldap://URLs are upgraded to a TLS connection using StartTLS as specified in https://tools.ietf.org/html/rfc28 30.	boolean.
ca	Optional trusted certificate authority bundle to use when making requests to the server. If empty, the default system roots are used.	string

Name	Description	Schema
groupUIDNameMapping	Optional direct mapping of LDAP group UIDs to OpenShift Container Platform Group names.	object
rfc2307	Holds the configuration for extracting data from an LDAP server set up in a fashion similar to RFC2307: first-class group and user entries, with group membership determined by a multi-valued attribute on the group entry listing its members.	v1.RFC2307Config
activeDirectory	Holds the configuration for extracting data from an LDAP server set up in a fashion similar to that used in Active Directory: first-class user entries, with group membership determined by a multi-valued attribute on members listing groups they are a member of.	v1.ActiveDirectoryConfig
augmentedActiveDirector y	Holds the configuration for extracting data from an LDAP server set up in a fashion similar to that used in Active Directory as described above, with one addition: first-class group entries exist and are used to hold metadata but not group membership.	v1.AugmentedActiveDirectoryCo nfig

13.7.2. v1.StringSource

StringSource allows specifying a string inline, or externally via environment variable or file. When it contains only a string value, it marshals to a simple JSON string.

Name	Description	Schema
value	Specifies the cleartext value, or an encrypted value if keyFile is specified.	string
env	Specifies an environment variable containing the cleartext value, or an encrypted value if the keyFile is specified.	string

Name	Description	Schema
file	References a file containing the cleartext value, or an encrypted value if a keyFile is specified.	string
keyFile	References a file containing the key to use to decrypt the value.	string

13.7.3. v1.LDAPQuery

LDAPQuery holds the options necessary to build an LDAP query.

Name	Description	Schema
baseDN	DN of the branch of the directory where all searches should start from.	string
scope	The (optional) scope of the search. Can be base (only the base object), one (all objects on the base level), sub (the entire subtree). Defaults to sub if not set.	string
derefAliases	The (optional) behavior of the search with regards to alisases. Can be never (never dereference aliases), search (only dereference in searching), base (only dereference in finding the base object), always (always dereference). Defaults to always if not set.	string
timeout	Holds the limit of time in seconds that any request to the server can remain outstanding before the wait for a response is given up. If this is 0, no client-side limit is imposed.	integer
filter	A valid LDAP search filter that retrieves all relevant entries from the LDAP server with the base DN.	string

Name	Description	Schema
pageSize	Maximum preferred page size, measured in LDAP entries. A page size of 0 means no paging will be done.	integer

13.7.4. v1.RFC2307Config

RFC2307Config holds the necessary configuration options to define how an LDAP group sync interacts with an LDAP server using the RFC2307 schema.

Name	Description	Schema
groupsQuery	Holds the template for an LDAP query that returns group entries.	v1.LDAPQuery
groupUIDAttribute	Defines which attribute on an LDAP group entry will be interpreted as its unique identifier. (ldapGroupUID)	string
groupNameAttributes	Defines which attributes on an LDAP group entry will be interpreted as its name to use for an OpenShift Container Platform group.	string array
groupMembershipAttribut es	Defines which attributes on an LDAP group entry will be interpreted as its members. The values contained in those attributes must be queryable by your UserUIDAttribute .	string array
usersQuery	Holds the template for an LDAP query that returns user entries.	v1.LDAPQuery
userUIDAttribute	Defines which attribute on an LDAP user entry will be interpreted as its unique identifier. It must correspond to values that will be found from the GroupMembershipAttributes .	string

Name	Description	Schema
userNameAttributes	Defines which attributes on an LDAP user entry will be used, in order, as its OpenShift Container Platform user name. The first attribute with a non-empty value is used. This should match your PreferredUsername setting for your LDAPPasswordIdentityPro vider.	string array
tolerateMemberNotFoundE rrors	Determines the behavior of the LDAP sync job when missing user entries are encountered. If true, an LDAP query for users that does not find any will be tolerated and an only and error will be logged. If false, the LDAP sync job will fail if a query for users doesn't find any. The default value is 'false'. Misconfigured LDAP sync jobs with this flag set to 'true' can cause group membership to be removed, so it is recommended to use this flag with caution.	boolean
tolerateMemberOutOfScop eErrors	Determines the behavior of the LDAP sync job when out-of-scope user entries are encountered. If true, an LDAP query for a user that falls outside of the base DN given for the all user query will be tolerated and only an error will be logged. If false, the LDAP sync job will fail if a user query would search outside of the base DN specified by the all user query. Misconfigured LDAP sync jobs with this flag set to true can result in groups missing users, so it is recommended to use this flag with caution.	boolean

13.7.5. v1.ActiveDirectoryConfig

ActiveDirectoryConfig holds the necessary configuration options to define how an LDAP group sync interacts with an LDAP server using the Active Directory schema.

Name	Description	Schema
users Q uery	Holds the template for an LDAP query that returns user entries.	v1.LDAPQuery
userNameAttributes	Defines which attributes on an LDAP user entry will be interpreted as its OpenShift Container Platform user name.	string array
groupMembershipAttribut es	Defines which attributes on an LDAP user entry will be interpreted as the groups it is a member of.	string array

13.7.6. v1.AugmentedActiveDirectoryConfig

AugmentedActiveDirectoryConfig holds the necessary configuration options to define how an LDAP group sync interacts with an LDAP server using the augmented Active Directory schema.

Name	Description	Schema
usersQuery	Holds the template for an LDAP query that returns user entries.	v1.LDAPQuery
userNameAttributes	Defines which attributes on an LDAP user entry will be interpreted as its OpenShift Container Platform user name.	string array
groupMembershipAttribut es	Defines which attributes on an LDAP user entry will be interpreted as the groups it is a member of.	string array
groupsQuery	Holds the template for an LDAP query that returns group entries.	v1.LDAPQuery
groupUIDAttribute	Defines which attribute on an LDAP group entry will be interpreted as its unique identifier. (ldapGroupUID)	string
groupNameAttributes	Defines which attributes on an LDAP group entry will be interpreted as its name to use for an OpenShift Container Platform group.	string array

CHAPTER 14. ADVANCED LDAP CONFIGURATION

14.1. OVERVIEW

OpenShift Container Platform Advanced Lightweight Directory Access Protocol (LDAP) Configuration covers the following topics:

- Setting up SSSD for LDAP Failover
- Configuring Form-Based Authentication
- Configuring Extended LDAP Attributes

14.2. SETTING UP SSSD FOR LDAP FAILOVER

14.2.1. Overview

OpenShift Container Platform provides an authentication provider for use with Lightweight Directory Access Protocol (LDAP) setups, but it can only connect to a single LDAP server. This can be problematic if that LDAP server becomes unavailable. System Security Services Daemon (SSSD) can be used to solve the issue.

Originally designed to manage local and remote authentication to the host operating system, SSSD can now be configured to provide identity, authentication, and authorization services to web services like OpenShift Container Platform. SSSD provides advantages over the built-in LDAP provider, including the ability to connect to any number of failover LDAP servers, as well as the ability to cache authentication attempts in case it can no longer reach any of those servers.

The setup for this configuration is advanced and requires a separate authentication server (also called an **authenticating proxy**) for OpenShift Container Platform to communicate with. This topic describes how to do this setup on a dedicated physical or virtual machine (VM), but the concepts are also applicable to a setup in a container.

14.2.2. Prerequisites for Authenticating Proxy Setup

- 1. Before starting setup, you need to know the following information about your LDAP server.
 - Whether the directory server is powered by FreeIPA, Active Directory, or another LDAP solution.
 - The Uniform Resource Identifier (URI) for the LDAP server (for example, Idap.example.com).
 - The location of the CA certificate for the LDAP server.
 - Whether the LDAP server corresponds to RFC 2307 or RFC2307bis for user groups.

2. Prepare the VMs:

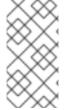

- proxy.example.com: A VM to use as the authenticating proxy. This machine must have at least SSSD 1.12.0 available, which means a fairly recent operating system. This topic uses a Red Hat Enterprise Linux 7.2 server for its examples.
- openshift.example.com: A VM to use to run OpenShift Container Platform.

NOTE

These VMs can be configured to run on the same system, but for the examples used in this topic they are kept separate.

14.2.3. Phase 1: Certificate Generation

NOTE

This phase generates certificate files that are valid for two years (or five years for the certification authority (CA) certificate). This can be altered with the --expire-days and --signer-expire-days options, but for security reasons, it is recommended to not make them greater than these values.

 To ensure that communication between the authenticating proxy and OpenShift Container Platform is trustworthy, create a set of Transport Layer Security (TLS) certificates to use during the other phases of this setup. In the OpenShift Container Platform system, start by using the auto-generated certificates created as part of running:

```
# openshift start \
    --public-master=https://openshift.example.com:8443 \
    --write-config=/etc/origin/
```

Among other things, this generates a /etc/origin/master/ca.{cert|key}. Use this signing certificate to generate keys to use on the authenticating proxy.

IMPORTANT

Ensure that any host names and interface IP addresses that need to access the proxy are listed. Otherwise, the HTTPS connection will fail.

2. Create a new CA to sign this client certificate:

```
# oadm ca create-signer-cert \
    --cert='/etc/origin/proxy/proxyca.crt' \
    --key='/etc/origin/proxy/proxyca.key' \
    --name='openshift-proxy-signer@UNIQUESTRING' \ 1
    --serial='/etc/origin/proxy/proxyca.serial.txt'
```

- Make UNIQUESTRING something unique.
- 3. Generate the API client certificate that the authenticating proxy will use to prove its identity to OpenShift Container Platform.

```
# oadm create-api-client-config \
     --certificate-authority='/etc/origin/proxy/proxyca.crt' \
     --client-dir='/etc/origin/proxy' \
     --signer-cert='/etc/origin/proxy/proxyca.crt' \
     --signer-key='/etc/origin/proxy/proxyca.key' \
     --signer-serial='/etc/origin/proxy/proxyca.serial.txt' \
     --user='system:proxy'
```

This prevents malicious users from impersonating the proxy and sending fake identities.

4. Copy the certificate and key information to the appropriate file for future steps:

```
# cat /etc/origin/proxy/system\:proxy.crt \
    /etc/origin/proxy/system\:proxy.key \
          /etc/origin/proxy/authproxy.pem
```

14.2.4. Phase 2: Authenticating Proxy Setup

This section guides you through the steps to authenticate the proxy setup.

14.2.4.1. Step 1: Copy Certificates

From *openshift.example.com*, securely copy the necessary certificates to the proxy machine:

```
# scp /etc/origin/master/ca.crt \
    root@proxy.example.com:/etc/pki/CA/certs/

# scp /etc/origin/proxy/proxy.example.com.crt \
    /etc/origin/proxy/authproxy.pem \
    root@proxy.example.com:/etc/pki/tls/certs/

# scp /etc/origin/proxy/proxy.example.com.key \
    root@proxy.example.com:/etc/pki/tls/private/
```

14.2.4.2. Step 2: SSSD Configuration

- Install a new VM with an operating system that includes 1.12.0 or later so that you can use the mod_identity_lookup module. The examples in this topic use a Red Hat Enterprise Linux 7.2 Server.
- 2. Install all of the necessary dependencies:

This gives you the needed SSSD and the web server components.

3. Edit the /etc/httpd/conf.modules.d/55-authnz_pam.conf file and remove the comment from the following:

```
LoadModule authnz_pam_module modules/mod_authnz_pam.so
```

4. Set up SSSD to authenticate this VM against the LDAP server. If the LDAP server is a FreelPA or Active Directory environment, then **realmd** can be used to join this machine to the domain.

```
# realm join ldap.example.com
```

For more advanced case, see the System-Level Authentication Guide

If you want to use SSSD to manage failover situations for LDAP, this can be configured by adding additional entries in /etc/sssd/sssd.conf on the Idap_uri line. Systems enrolled with FreeIPA can automatically handle failover using DNS SRV records.

5. Restart SSSD to ensure that all of the changes are applied properly:

```
$ systemctl restart sssd.service
```

6. Test that the user information can be retrieved properly:

```
$ getent passwd <username>
username:*:12345:12345:Example User:/home/username:/usr/bin/bash
```

7. Attempt to log into the VM as an LDAP user and confirm that the authentication is properly set up. This can be done via the local console or a remote service such as SSH.

NOTE

If you do not want LDAP users to be able to log into this machine, it is recommended to modify /etc/pam.d/system-auth and /etc/pam.d/password-auth to remove the lines containing pam_sss.so.

14.2.4.3. Step 3: Apache Configuration

You need to set up Apache to communicate with SSSD. Create a PAM stack file for use with Apache. To do so:

1. Create the /etc/pam.d/openshift file and add the following contents:

```
auth required pam_sss.so
account required pam_sss.so
```

This configuration enables PAM (the pluggable authentication module) to use **pam_sss.so** to determine authentication and access control when an authentication request is issued for the **openshift** stack.

2. Configure the Apache *httpd.conf*. The steps in this section focus on setting up the challenge authentication, which is useful for logging in with **oc login** and similar automated tools.

NOTE

Configuring Form-Based Authentication explains how to set up a graphical login using SSSD as well, but it requires the rest of this setup as a prerequisite.

3. Create the new file *openshift-proxy.conf* in /etc/httpd/conf.d (substituting the correct host names where indicated):

```
LoadModule request_module modules/mod_request.so
LoadModule lookup identity module modules/mod_lookup_identity.so
# Nothing needs to be served over HTTP. This virtual host simply
redirects to
# HTTPS.
<VirtualHost *:80>
  DocumentRoot /var/www/html
  RewriteEngine
                             0n
  RewriteRule
                ^(.*)$
                           https://%{HTTP_HOST}$1 [R,L]
</VirtualHost>
<VirtualHost *:443>
  # This needs to match the certificates you generated. See the CN
and X509v3
  # Subject Alternative Name in the output of:
  # openssl x509 -text -in /etc/pki/tls/certs/proxy.example.com.crt
  ServerName proxy.example.com
  DocumentRoot /var/www/html
  SSLEngine on
  SSLCertificateFile /etc/pki/tls/certs/proxy.example.com.crt
  SSLCertificateKeyFile /etc/pki/tls/private/proxy.example.com.key
  SSLCACertificateFile /etc/pki/CA/certs/ca.crt
  # Send logs to a specific location to make them easier to find
  ErrorLog logs/proxy_error_log
  TransferLog logs/proxy_access_log
  LogLevel warn
  SSLProxyEngine on
  SSLProxyCACertificateFile /etc/pki/CA/certs/ca.crt
  # It's critical to enforce client certificates on the Master.
Otherwise
  # requests could spoof the X-Remote-User header by accessing the
  # /oauth/authorize endpoint directly.
  SSLProxyMachineCertificateFile /etc/pki/tls/certs/authproxy.pem
  # Send all requests to the console
  RewriteEngine
                 ^/console(.*)$
  RewriteRule
                                     https://%
{HTTP_HOST}:8443/console$1 [R,L]
  # In order to using the challenging-proxy an X-Csrf-Token must be
present.
  RewriteCond %{REQUEST_URI} ^/challenging-proxy
  RewriteCond %{HTTP:X-Csrf-Token} ^$ [NC]
  RewriteRule ^.* - [F,L]
```

NOTE

Configuring Form-Based Authentication explains how to add the **login-proxy** block to support form authentication.

4. Set a boolean to tell SELinux that it is acceptable for Apache to contact the PAM subsystem:

```
# setsebool -P allow_httpd_mod_auth_pam on
```

5. Start up Apache:

```
# systemctl start httpd.service
```

14.2.5. Phase 3: OpenShift Container Platform Configuration

This section describes how to set up an OpenShift Container Platform server from scratch in an "all in one" configuration. Master and Node Configuration provides more information on alternate configurations.

Modify the default configuration to use the new identity provider just created. To do so:

- 1. Modify the /etc/origin/master/master-config.yaml file.
- 2. Scan through it and locate the identityProviders section and replace it with:

```
identityProviders:
    name: any_provider_name
    challenge: true
    login: false
    mappingMethod: claim
    provider:
        apiVersion: v1
        kind: RequestHeaderIdentityProvider
        challengeURL: "https://proxy.example.com/challenging-proxy/oauth/authorize?${query}"
```

clientCA: /etc/origin/proxy/proxyca.crt
headers:

- X-Remote-User

NOTE

Configuring Form-Based Authentication explains how to add the login URL to support web logins.

Configuring Extended LDAP Attributes explains how to add the email and fullname attributes. Note that the full-name attributes are only stored to the database on the first login.

3. Start OpenShift Container Platform with the updated configuration:

```
# openshift start \
    --public-master=https://openshift.example.com:8443 \
    --master-config=/etc/origin/master/master-config.yaml \
    --node-config=/etc/origin/node-node1.example.com/node-config.yaml
```

4. Test logins:

```
oc login https://openshift.example.com:8443
```

It should now be possible to log in with only valid LDAP credentials.

14.3. CONFIGURING FORM-BASED AUTHENTICATION

14.3.1. Overview

This topic builds upon Setting up SSSD for LDAP Failover and describes how to set up form-based authentication for signing into the OpenShift Container Platform web console.

14.3.2. Prepare a Login Page

The OpenShift Container Platform upstream repositories have a template for forms. Copy that to your authenticating proxy on *proxy.example.com*:

```
# curl -o /var/www/html/login.html \
    https://raw.githubusercontent.com/openshift/openshift-
extras/master/misc/form_auth/login.html
```

Modify this .html file to change the logo icon and "Welcome" content for your environment.

14.3.3. Install Another Apache Module

To intercept form-based authentication, install an Apache module:

```
# yum -y install mod_intercept_form_submit
```

14.3.4. Apache Configuration

- Modify /etc/httpd/conf.modules.d/55-intercept_form_submit.conf and uncomment the LoadModule line.
- 2. Add a new section to your *openshift-proxy.conf* file inside the <VirtualHost *:443> block.

```
<Location /login-proxy/oauth/authorize>
  # Insert your backend server name/ip here.
ProxyPass https://openshift.example.com:8443/oauth/authorize

InterceptFormPAMService openshift
InterceptFormLogin httpd_username
InterceptFormPassword httpd_password

RewriteCond %{REQUEST_METHOD} GET
RewriteRule ^.*$ /login.html [L]
</Location>
```

This tells Apache to listen for POST requests on the /login-proxy/oauth/authorize and to pass the user name and password over to the openshift PAM service.

3. Restart the service and move back over to the OpenShift Container Platform configuration.

14.3.5. OpenShift Container Platform Configuration

1. In the master-config.yaml file, update the identityProviders section:

- Note that login is set to true, not false.
- Newly added line.
- 2. Restart OpenShift Container Platform with the updated configuration.

NOTE

You should be able to browse to https://openshift.example.com:8443 and use your LDAP credentials to sign in via the login form.

14.4. CONFIGURING EXTENDED LDAP ATTRIBUTES

14.4.1. Overview

This topic builds upon Setting up SSSD for LDAP Failover and Configuring Form-Based Authentication and focuses on configuring extended Lightweight Directory Access Protocol (LDAP) attributes.

14.4.2. Prerequisites

- SSSD 1.12.0 or later. This is available on Red Hat Enterprise Linux 7.0 and later.
- mod_lookup_identity 0.9.4 or later.
 - The required version is not yet available on any version of Red Hat Enterprise Linux.
 However, compatible packages (RPMs) are available from upstream until they arrive in Red Hat Enterprise Linux.

14.4.3. Configuring SSSD

You need to ask System Security Services Daemon (SSSD) to look up attributes in LDAP that it normally does not care about for simple system-login use-cases. In the case of OpenShift Container Platform, there is only one such attribute: email. So, you need to:

 Modify the [domain/DOMAINNAME] section of /etc/sssd/sssd.conf on the authenticating proxy and add this attribute:

```
[domain/example.com]
...
ldap_user_extra_attrs = mail
```

2. Tell SSSD that it is acceptable for this attribute to be retrieved by Apache. Add the following two lines to the [ifp] section of /etc/sssd/sssd.conf:

```
[ifp]
user_attributes = +mail
allowed_uids = apache, root
```

3. Restart SSSD:

```
# systemctl restart sssd.service
```

4. Test this configuration.

14.4.4. Configuring Apache

Now that SSSD is set up and successfully serving extended attributes, configure the web server to ask for them and to insert them in the correct places.

1. Enable the module to be loaded by Apache. To do so, modify /etc/httpd/conf.modules.d/55-lookup_identity.conf and uncomment the line:

```
LoadModule lookup_identity_module modules/mod_lookup_identity.so
```

2. Set an SELinux boolean so that SElinux allows Apache to connect to SSSD over D-BUS:

```
# setsebool -P httpd_dbus_sssd on
```

3. Edit /etc/httpd/conf.d/openshift-proxy.conf and add the following lines inside the <ProxyMatch /oauth/authorize> section:

```
<ProxyMatch /oauth/authorize>
AuthName openshift

LookupOutput Headers 1
LookupUserAttr mail X-Remote-User-Email 2
LookupUserGECOS X-Remote-User-Display-Name 3

RequestHeader set X-Remote-User %{REMOTE_USER}s env=REMOTE_USER
</ProxyMatch>
```

- 1 2 3 Added line.
- 4. Restart Apache to pick up the changes:

```
# systemctl restart httpd.service
```

14.4.5. Configuring OpenShift Container Platform

Tell OpenShift Container Platform where to find these new attributes during login. To do so:

1. Edit the /etc/origin/master/master-config.yaml file and add the following lines to the identityProviders section:

```
identityProviders:
 - name: sssd
challenge: true
 login: true
mappingMethod: claim
 provider:
   apiVersion: v1
   kind: RequestHeaderIdentityProvider
   challengeURL: "https://proxy.example.com/challenging-
proxy/oauth/authorize?${query}"
   loginURL: "https://proxy.example.com/login-proxy/oauth/authorize?
${query}"
/home/example/workspace/openshift/configs/openshift.example.com/prox
y/proxyca.crt
   headers:
   - X-Remote-User
   emailHeaders: 1
   - X-Remote-User-Email (2)
   nameHeaders: (3)
   - X-Remote-User-Display-Name 4
```

2. Launch OpenShift Container Platform with this updated configuration and log in to the web as a new user.

You should see their full name appear in the upper-right of the screen. You can also verify with oc get identities -o yaml that both email addresses and full names are available.

14.4.6. Debugging Notes

Currently, OpenShift Container Platform only saves these attributes to the user at the time of the first login and does not update them again after that. So, while you are testing (and only while testing), run oc delete users, identities --all to clear the identities out so you can log in again.

CHAPTER 15. CONFIGURING THE SDN

15.1. OVERVIEW

The OpenShift SDN enables communication between pods across the OpenShift Container Platform cluster, establishing a *pod network* Two SDN plug-ins are currently available (ovs-subnet and ovs-multitenant), which provide different methods for configuring the pod network. A third (ovs-networkpolicy) is currently in Tech Preview.

15.2. CONFIGURING THE POD NETWORK WITH ANSIBLE

For initial advanced installations, the **ovs-subnet** plug-in is installed and configured by default, though it can be overridden during installation using the **os_sdn_network_plugin_name** parameter, which is configurable in the Ansible inventory file.

Example 15.1. Example SDN Configuration with Ansible

```
# Configure the multi-tenant SDN plugin (default is 'redhat/openshift-
ovs-subnet')
# os_sdn_network_plugin_name='redhat/openshift-ovs-multitenant'
# Configure the NetworkPolicy SDN plugin (Tech Preview)
# os_sdn_network_plugin_name='redhat/openshift-ovs-networkpolicy'
# Disable the OpenShift SDN plugin
# openshift_use_openshift_sdn=False
# Configure SDN cluster network CIDR block. This network block should
# be a private block and should not conflict with existing network
# blocks in your infrastructure that pods may require access to.
# Can not be changed after deployment.
#osm_cluster_network_cidr=10.1.0.0/16
# default subdomain to use for exposed routes
#openshift_master_default_subdomain=apps.test.example.com
# Configure SDN cluster network and kubernetes service CIDR blocks.
# network blocks should be private and should not conflict with network
# in your infrastructure that pods may require access to. Can not be
changed
# after deployment.
#osm_cluster_network_cidr=10.1.0.0/16
#openshift_portal_net=172.30.0.0/16
# Configure number of bits to allocate to each host's subnet e.g. 8
# would mean a /24 network on the host.
#osm_host_subnet_length=8
# This variable specifies the service proxy implementation to use:
# either iptables for the pure-iptables version (the default),
# or userspace for the userspace proxy.
#openshift_node_proxy_mode=iptables
```

For initial quick installations, the **ovs-subnet** plug-in is installed and configured by default as well, and can be reconfigured post-installation using the **networkConfig** stanza of the **master-config.yaml** file.

15.3. CONFIGURING THE POD NETWORK ON MASTERS

Cluster administrators can control pod network settings on masters by modifying parameters in the networkConfig section of the master configuration file (located at /etc/origin/master/master-config.yaml by default):

networkConfig:

clusterNetworkCIDR: 10.128.0.0/14 1

hostSubnetLength: 9 (2)

networkPluginName: "redhat/openshift-ovs-subnet" 3

serviceNetworkCIDR: 172.30.0.0/16 4

- Cluster network for node IP allocation
- Number of bits for pod IP allocation within a node
- 3 Set to redhat/openshift-ovs-subnet for the ovs-subnet plug-in, redhat/openshift-ovs-multitenant for the ovs-multitenant plug-in, or redhat/openshift-ovs-networkpolicy for the ovs-networkpolicy plug-in
- Service IP allocation for the cluster

IMPORTANT

The serviceNetworkCIDR and hostSubnetLength values cannot be changed after the cluster is first created, and clusterNetworkCIDR can only be changed to be a larger network that still contains the original network. For example, given the default value of 10.128.0.0/14, you could change clusterNetworkCIDR to 10.128.0.0/9 (i.e., the entire upper half of net 10) but not to 10.64.0.0/16, because that does not overlap the original value.

15.4. CONFIGURING THE POD NETWORK ON NODES

Cluster administrators can control pod network settings on nodes by modifying parameters in the networkConfig section of the node configuration file (located at /etc/origin/node/node-config.yaml by default):

networkConfig:

mtu: 1450 1

networkPluginName: "redhat/openshift-ovs-subnet" 2

- Maximum transmission unit (MTU) for the pod overlay network
- Set to redhat/openshift-ovs-subnet for the ovs-subnet plug-in, redhat/openshift-ovs-multitenant for the ovs-multitenant plug-in, or redhat/openshift-ovs-networkpolicy for the ovs-networkpolicy plug-in

15.5. MIGRATING BETWEEN SDN PLUG-INS

If you are already using one SDN plug-in and want to switch to another:

- Change the networkPluginName parameter on all masters and nodes in their configuration files.
- 2. Restart the **atomic-openshift-master** service on masters and the **atomic-openshift-node** service on nodes.
- 3. If you are switching from an OpenShift SDN plug-in to a third-party plug-in, then clean up OpenShift SDN-specific artifacts:

```
$ oc delete clusternetwork --all
$ oc delete hostsubnets --all
$ oc delete netnamespaces --all
```

When switching from the **ovs-subnet** to the **ovs-multitenant** OpenShift SDN plug-in, all the existing projects in the cluster will be fully isolated (assigned unique VNIDs). Cluster administrators can choose to modify the project networks using the administrator CLI.

Check VNIDs by running:

\$ oc get netnamespace

15.6. EXTERNAL ACCESS TO THE CLUSTER NETWORK

If a host that is external to OpenShift Container Platform requires access to the cluster network, you have two options:

- 1. Configure the host as an OpenShift Container Platform node but mark it unschedulable so that the master does not schedule containers on it.
- 2. Create a tunnel between your host and a host that is on the cluster network.

Both options are presented as part of a practical use-case in the documentation for configuring routing from an edge load-balancer to containers within OpenShift SDN .

15.7. USING FLANNEL

As an alternative to the default SDN, OpenShift Container Platform also provides Ansible playbooks for installing **flannel**-based networking. This is useful if running OpenShift Container Platform within a cloud provider platform that also relies on SDN, such as Red Hat OpenStack Platform, and you want to avoid encapsulating packets twice through both platforms.

IMPORTANT

This is only supported for OpenShift Container Platform on Red Hat OpenStack Platform.

IMPORTANT

Neutron port security must be configured, even when security groups are not being used.

To enable **flannel** within your OpenShift Container Platform cluster:

- Neutron port security controls must be configured to be compatible with Flannel. The default configuration of Red Hat OpenStack Platform disables user control of port_security.
 Configure Neutron to allow users to control the port_security setting on individual ports.
 - a. On the Neutron servers, add the following to the /etc/neutron/plugins/ml2/ml2_conf.ini file:

```
[ml2]
...
extension_drivers = port_security
```

b. Then, restart the Neutron services:

```
service neutron-ovs-cleanup restart
service neutron-metadata-agentrestart
service neutron-13-agent restart
service neutron-plugin-openvswitch-agent restart
service neutron-vpn-agent restart
service neutron-vpn-agent restart
```

2. Set the following variables in your Ansible inventory file before running the installation:

```
openshift_use_openshift_sdn=false 1
openshift_use_flannel=true 2
flannel_interface=eth0
```

- Set openshift_use_openshift_sdn to false to disable the default SDN.
- 2 Set openshift_use_flannel to true to enable flannel in place.
- 3. Optionally, you can specify the interface to use for inter-host communication using the flannel_interface variable. Without this variable, the OpenShift Container Platform installation uses the default interface.

CHAPTER 16. CONFIGURING NUAGE SDN

16.1. NUAGE SDN AND OPENSHIFT CONTAINER PLATFORM

Nuage Networks Virtualized Services Platform (VSP) provides virtual networking and software-defined networking (SDN) infrastructure to Docker container environments that simplifies IT operations and expands OpenShift Container Platform's native networking capabilities.

Nuage Networks VSP supports Docker-based applications running on OpenShift Container Platform to accelerate the provisioning of virtual networks between pods and traditional workloads, and to enable security policies across the entire cloud infrastructure. VSP allows for the automation of security appliances to include granular security and microsegmentation policies for container applications.

Integrating VSP with the OpenShift Container Platform application workflow allows business applications to be quickly turned up and updated by removing the network lag faced by DevOps teams. VSP supports different workflows with OpenShift Container Platform in order to accommodate scenarios where users can choose ease-of-use or complete control using policy-based automation.

See Networking for more information on how VSP is integrated with OpenShift Container Platform.

16.2. DEVELOPER WORKFLOW

This workflow is used in developer environments and requires little input from the developer in setting up the networking. In this workflow, **nuage-openshift-monitor** is responsible for creating the VSP constructs (Zone, Subnets, etc.) needed to provide appropriate policies and networking for pods created in an OpenShift Container Platform project. When a project is created, a default zone and default subnet for that project are created by **nuage-openshift-monitor**. When the default subnet created for a given project gets depleted, **nuage-openshift-monitor** dynamically creates additional subnets.

NOTE

A separate VSP Zone is created for each OpenShift Container Platform project ensuring isolation amongst the projects.

16.3. OPERATIONS WORKFLOW

This workflow is used by operations teams rolling out applications. In this workflow, the network and security policies are first configured on the VSD in accordance with the rules set by the organization to deploy applications. Administrative users can potentially create multiple zones and subnets and map them to the same project using labels. While spinning up the pods, the user can use the Nuage Labels to specify what network a pod needs to attach to and what network policies need to be applied to it. This allows for deployments where inter- and intra-project traffic can be controlled in a fine-grained manner. For example, inter-project communication is enabled on a project by project basis. This may be used to connect projects to common services that are deployed in a shared project.

16.4. INSTALLATION

The VSP integration with OpenShift Container Platform works for both virtual machines (VMs) and bare metal OpenShift Container Platform installations.

16.4.1. Installation for a Single Master

In the Ansible nodes file, specify the following parameters in order to set up Nuage VSP as the network plug-in:

```
# Nuage specific parameters
 openshift_use_openshift_sdn=False
 openshift_use_nuage=True
 os_sdn_network_plugin_name='nuage/vsp-openshift'
 openshift_node_proxy_mode='userspace'
 nuage_openshift_monitor_rest_server_port=9443
# VSP related parameters
vsd_api_url=https://192.168.103.200:8443
vsp_version=v4_0
 enterprise=nuage
 domain=openshift
vsc_active_ip=192.168.103.201
vsc_standby_ip=192.168.103.202
 uplink_interface=eth0
# rpm locations
 nuage_openshift_rpm=http://location_of_rpm_server/openshift/RPMS/x86_64/n
uage-openshift-monitor-4.0.X.1830.el7.centos.x86_64.rpm
vrs_rpm=http://location_of_rpm_server/openshift/RPMS/x86_64/nuage-
openvswitch-4.0.X.225.el7.x86_64.rpm
 plugin_rpm=http://location_of_rpm_server/openshift/RPMS/x86_64/vsp-
openshift-4.0.X1830.el7.centos.x86_64.rpm
# Optional parameters
 nuage_interface_mtu=1460
 nuage_master_adminusername=admin
 nuage_master_adminuserpasswd=admin
 nuage_master_cspadminpasswd=admin
 nuage_openshift_monitor_log_dir=/var/log/nuage-openshift-monitor
 # Required for brownfield install (where a {product-title} cluster exists
without Nuage as the networking plugin)
 nuage_dockker_bridge=lbr0
```

16.4.2. Installation for Multiple Masters (HA)

An environment with High Availability (HA) can be configured with multiple masters and multiple nodes.

Nuage VSP integration in multi-master mode only supports the native HA configuration method described in this section. This can be combined with any load balancing solution, the default being HAProxy. The inventory file contains three master hosts, the nodes, an etcd server, and a host that functions as the HAProxy to balance the master API on all master hosts. The HAProxy host is defined in the [lb] section of the inventory file enabling Ansible to automatically install and configure HAProxy as the load balancing solution.

In the Ansible nodes file, the following parameters need to be specified in order to setup Nuage VSP as the network plug-in:

Create and OSEv3 group that contains masters, nodes, load-balancers, and etcd hosts

```
masters
 nodes
 etcd
 1b
 # Nuage specific parameters
openshift_use_openshift_sdn=False
 openshift_use_nuage=True
 os_sdn_network_plugin_name='nuage/vsp-openshift'
 openshift_node_proxy_mode='userspace'
# VSP related parameters
vsd_api_url=https://192.168.103.200:8443
vsp_version=v4_0
enterprise=nuage
 domain=openshift
vsc_active_ip=192.168.103.201
vsc_standby_ip=192.168.103.202
uplink_interface=eth0
# rpm locations
nuage_openshift_rpm=http://location_of_rpm_server/openshift/RPMS/x86_64/n
uage-openshift-monitor-4.0.X.1830.el7.centos.x86_64.rpm
vrs_rpm=http://location_of_rpm_server/openshift/RPMS/x86_64/nuage-
openvswitch-4.0.X.225.el7.x86_64.rpm
 plugin_rpm=http://location_of_rpm_server/openshift/RPMS/x86_64/vsp-
openshift-4.0.X1830.el7.centos.x86_64.rpm
# Required for Nuage Monitor REST server and HA
 openshift master cluster method=native
 openshift_master_cluster_hostname=lb.nuageopenshift.com
 openshift_master_cluster_public_hostname=lb.nuageopenshift.com
 nuage_openshift_monitor_rest_server_port=9443
# Optional parameters
 nuage_interface_mtu=1460
nuage_master_adminusername='admin's user-name'
nuage_master_adminuserpasswd='admin's password'
 nuage_master_cspadminpasswd='csp admin password'
 nuage_openshift_monitor_log_dir=/var/log/nuage-openshift-monitor
# Required for brownfield install (where a {product-title} cluster exists
without Nuage as the networking plugin)
 nuage_dockker_bridge=lbr0
# Specify master hosts
 [masters]
 fqdn_of_master_1
 fqdn_of_master_2
fqdn_of_master_3
# Specify load balancer host
 [lb]
 fqdn_of_load_balancer
```

CHAPTER 17. CONFIGURING FOR AWS

17.1. OVERVIEW

OpenShift Container Platform can be configured to access an AWS EC2 infrastructure, including using AWS volumes as persistent storage for application data. After AWS is configured properly, some additional configurations will need to be completed on the OpenShift Container Platform hosts.

17.2. CONFIGURING AWS VARIABLES

To set the required AWS variables, create a /etc/aws/aws.conf file with the following contents on all of your OpenShift Container Platform hosts, both masters and nodes:

```
[Global]
Zone = us-east-1c 1
```

This is the Availability Zone of your AWS Instance and where your EBS Volume resides; this information is obtained from the AWS Managment Console.

17.3. CONFIGURING OPENSHIFT CONTAINER PLATFORM MASTERS FOR AWS

You can set the AWS configuration on your OpenShift Container Platform master hosts in two ways:

- using Ansible and the advanced installation tool
- manually, by modifying the *master-config.yaml* file

17.3.1. Configuring OpenShift Container Platform for AWS with Ansible

During advanced installations, AWS can be configured using the openshift_cloudprovider_aws_access_key, openshift_cloudprovider_aws_secret_key, and openshift_cloudprovider_kind parameters, which are configurable in the inventory file.

Example AWS Configuration with Ansible

```
# Cloud Provider Configuration
#
# Note: You may make use of environment variables rather than store
# sensitive configuration within the ansible inventory.
# For example:
#openshift_cloudprovider_aws_access_key="{{
lookup('env', 'AWS_ACCESS_KEY_ID') }}"
#openshift_cloudprovider_aws_secret_key="{{
lookup('env', 'AWS_SECRET_ACCESS_KEY') }}"
#
# AWS (Using API Credentials)
#openshift_cloudprovider_kind=aws
#openshift_cloudprovider_aws_access_key=aws_access_key_id
#openshift_cloudprovider_aws_secret_key=aws_secret_access_key
#
# AWS (Using IAM Profiles)
```

#openshift_cloudprovider_kind=aws
Note: IAM roles must exist before launching the instances.

NOTE

When Ansible configures AWS, the following files are created for you:

- /etc/aws/aws.conf
- /etc/origin/master/master-config.yaml
- /etc/origin/node/node-config.yaml
- /etc/sysconfig/atomic-openshift-master
- /etc/sysconfig/atomic-openshift-node

17.3.2. Manually Configuring OpenShift Container Platform Masters for AWS

Edit or create the master configuration file on all masters (/etc/origin/master/master-config.yaml by default) and update the contents of the apiServerArguments and controllerArguments sections:

```
kubernetesMasterConfig:
...
apiServerArguments:
    cloud-provider:
    - "aws"
    cloud-config:
    - "/etc/aws/aws.conf"
controllerArguments:
    cloud-provider:
    - "aws"
    cloud-config:
    - "/etc/aws/aws.conf"
```

IMPORTANT

When triggering a containerized installation, only the directories of /etc/origin and /var/lib/origin are mounted to the master and node container. Therefore, aws.conf should be in /etc/origin/instead of /etc/.

17.3.3. Manually Configuring OpenShift Container Platform Nodes for AWS

Edit or create the node configuration file on all nodes (/etc/origin/node/node-config.yaml by default) and update the contents of the kubeletArguments section:

```
kubeletArguments:
   cloud-provider:
    - "aws"
   cloud-config:
    - "/etc/aws/aws.conf"
```

IMPORTANT

When triggering a containerized installation, only the directories of /etc/origin and /var/lib/origin are mounted to the master and node container. Therefore, aws.conf should be in /etc/origin/instead of /etc/.

17.4. SETTING KEY VALUE ACCESS PAIRS

Make sure the following environment variables are set in the /etc/sysconfig/atomic-openshift-master file on masters and the /etc/sysconfig/atomic-openshift-node file on nodes:

```
AWS_ACCESS_KEY_ID=<key_ID>
AWS_SECRET_ACCESS_KEY=<secret_key>
```

NOTE

Access keys are obtained when setting up your AWS IAM user.

17.5. APPLYING CONFIGURATION CHANGES

Start or restart OpenShift Container Platform services on all master and node hosts to apply your configuration changes:

```
# systemctl restart atomic-openshift-master
# systemctl restart atomic-openshift-node
```

Switching from not using a cloud provider to using a cloud provider produces an error message. Adding the cloud provider tries to delete the node because the node switches from using the hostname as the externalID (which would have been the case when no cloud provider was being used) to using the AWS instance-id (which is what the AWS cloud provider specifies). To resolve this issue:

- 1. Log in to the CLI as a cluster administrator.
- 2. Delete the nodes:

```
$ oc delete node <node_name>
```

- 3. On each node host, restart the atomic-openshift-node service.
- 4. Add back any labels on each node that you previously had.

CHAPTER 18. CONFIGURING FOR OPENSTACK

18.1. OVERVIEW

When deployed on OpenStack, OpenShift Container Platform can be configured to access OpenStack infrastructure, including using OpenStack Cinder volumes as persistent storage for application data.

18.2. CONFIGURING OPENSTACK VARIABLES

To set the required OpenStack variables, create a /etc/cloud.conf file with the following contents on all of your OpenShift Container Platform hosts, both masters and nodes:

```
[Global]
auth-url = <0S_AUTH_URL>
username = <0S_USERNAME>
password = <password>
domain-id = <0S_USER_DOMAIN_ID>
tenant-id = <0S_TENANT_ID>
region = <0S_REGION_NAME>

[LoadBalancer]
subnet-id = <UUID of the load balancer subnet>
```

Consult your OpenStack administrators for values of the **OS**_ variables, which are commonly used in OpenStack configuration.

18.3. CONFIGURING OPENSHIFT CONTAINER PLATFORM MASTERS FOR OPENSTACK

You can set an OpenStack configuration on your OpenShift Container Platform master and node hosts in two different ways:

- Using Ansible and the advanced installation tool
- Manually, by modifying the *master-config.yaml* and *node-config.yaml* files.

18.3.1. Configuring OpenShift Container Platform for OpenStack with Ansible

During advanced installations, OpenStack can be configured using the following parameters, which are configurable in the inventory file:

- openshift_cloudprovider_kind
- openshift_cloudprovider_openstack_auth_url
- openshift_cloudprovider_openstack_username
- openshift_cloudprovider_openstack_password
- openshift_cloudprovider_openstack_domain_id
- openshift_cloudprovider_openstack_domain_name

- openshift_cloudprovider_openstack_tenant_id
- openshift_cloudprovider_openstack_tenant_name
- openshift_cloudprovider_openstack_region
- openshift_cloudprovider_openstack_lb_subnet_id

Example 18.1. Example OpenStack Configuration with Ansible

```
# Cloud Provider Configuration
# Note: You may make use of environment variables rather than store
# sensitive configuration within the ansible inventory.
# For example:
#openshift_cloudprovider_openstack_username="{{ lookup('env', 'USERNAME')}
#openshift_cloudprovider_openstack_password="{{ lookup('env', 'PASSWORD')}
}}"
# Openstack
#openshift_cloudprovider_kind=openstack
#openshift_cloudprovider_openstack_auth_url=http://openstack.example.com
:35357/v2.0/
#openshift_cloudprovider_openstack_username=username
#openshift_cloudprovider_openstack_password=password
#openshift_cloudprovider_openstack_domain_id=domain_id
#openshift_cloudprovider_openstack_domain_name=domain_name
#openshift_cloudprovider_openstack_tenant_id=tenant_id
#openshift_cloudprovider_openstack_tenant_name=tenant_name
#openshift_cloudprovider_openstack_region=region
#openshift_cloudprovider_openstack_lb_subnet_id=subnet_id
```

18.3.2. Manually Configuring OpenShift Container Platform Masters for OpenStack

Edit or create the master configuration file on all masters (/etc/origin/master/master-config.yaml by default) and update the contents of the apiServerArguments and controllerArguments sections:

```
kubernetesMasterConfig:
...
apiServerArguments:
    cloud-provider:
    - "openstack"
    cloud-config:
    - "/etc/cloud.conf"
controllerArguments:
    cloud-provider:
    - "openstack"
    cloud-config:
    - "/etc/cloud.conf"
```

IMPORTANT

When triggering a containerized installation, only the directories of /etc/origin and /var/lib/origin are mounted to the master and node container. Therefore, cloud.conf should be in /etc/origin/instead of /etc/.

18.3.3. Manually Configuring OpenShift Container Platform Nodes for OpenStack

Edit or create the node configuration file on all nodes (/etc/origin/node/node-config.yaml by default) and update the contents of the kubeletArguments and nodeName sections:

nodeName: <instance_name> 1 kubeletArguments: cloud-provider: - "openstack" cloud-config: - "/etc/cloud.conf"

Name of the OpenStack instance where the node runs (i.e., name of the virtual machine)

IMPORTANT

When triggering a containerized installation, only the directories of /etc/origin and /var/lib/origin are mounted to the master and node container. Therefore, cloud.conf should be in /etc/origin/instead of /etc/.

CHAPTER 19. CONFIGURING FOR GCE

19.1. OVERVIEW

OpenShift Container Platform can be configured to access a Google Compute Engine (GCE) infrastructure, including using GCE volumes as persistent storage for application data. After GCE is configured properly, some additional configurations will need to be completed on the OpenShift Container Platform hosts.

19.2. CONFIGURING MASTERS

You can set the GCE configuration on your OpenShift Container Platform master hosts in two ways:

- Using Ansible and the advanced installation tool.
- Manually by modifying the *master-config.yaml* file.

19.2.1. Configuring OpenShift Container Platform Masters for GCE with Ansible

During advanced installations, GCE can be configured using the openshift_cloudprovider_kind parameter, which is configurable in the inventory file.

Example GCE Configuration with Ansible

```
# Cloud Provider Configuration
#
openshift_cloudprovider_kind=gce
```

NOTE

When Ansible configures GCE, the following files are created for you:

- /etc/origin/cloudprovider/gce.conf
- /etc/origin/master/master-config.yaml
- /etc/origin/node/node-config.yaml

The advanced installation configures multizone support by default. If you want single-zone support, edit the /etc/origin/cloudprovider/gce.conf as shown in Configuring Multizone Support in a GCE Deployment.

19.2.2. Manually Configuring OpenShift Container Platform Masters for GCE

To configure the OpenShift Container Platform masters for GCE:

 Edit or create the master configuration file (/etc/origin/master/master-config.yaml by default) on all masters and update the contents of the apiServerArguments and controllerArguments sections:

```
kubernetesMasterConfig:
    ...
    apiServerArguments:
```

```
cloud-provider:
    - "gce"
    cloud-config:
    - "/etc/origin/cloudprovider/gce.conf"
controllerArguments:
    cloud-provider:
    - "gce"
    cloud-config:
    - "/etc/origin/cloudprovider/gce.conf"
```

IMPORTANT

When triggering a containerized installation, only the directories of /etc/origin and /var/lib/origin are mounted to the master and node container. Therefore, master-config.yaml should be in /etc/origin/master instead of /etc/.

2. Start or restart the OpenShift Container Platform services:

systemctl restart atomic-openshift-master

19.3. CONFIGURING NODES

To configure the OpenShift Container Platform nodes for GCE:

1. Edit or create the node configuration file (/etc/origin/node/node-config.yaml by default) on all nodes and update the contents of the kubeletArguments section:

```
kubeletArguments:
  cloud-provider:
    - "gce"
  cloud-config:
    - "/etc/origin/cloudprovider/gce.conf"
```

IMPORTANT

When triggering a containerized installation, only the directories of /etc/origin and /var/lib/origin are mounted to the master and node container. Therefore, node-config.yaml should be in /etc/origin/node instead of /etc/.

2. Start or restart the OpenShift Container Platform services all nodes.

 ${\tt\#\ systemctl\ restart\ atomic-openshift-node}$

19.4. CONFIGURING MULTIZONE SUPPORT IN A GCE DEPLOYMENT

If manually congifuring GCE, multizone support is not configured by default.

NOTE

The advanced installation configures multizone support by default.

If you want multizone support:

- 1. Edit or create a /etc/origin/cloudprovider/gce.conf file on all of your OpenShift Container Platform hosts, both masters and nodes.
- 2. Add the following contents:

```
[Global]
multizone = true
```

3. Start or restart the OpenShift Container Platform services on the master and all nodes.

```
# systemctl restart atomic-openshift-master
# systemctl restart atomic-openshift-node
```

To return to single-zone support, set the multizone value to false.

CHAPTER 20. CONFIGURING FOR AZURE

20.1. OVERVIEW

OpenShift Container Platform can be configured to access an Azure infrastructure, including using Azure disk as persistent storage for application data. After Azure is configured properly, some additional configurations need to be completed on the OpenShift Container Platform hosts.

20.2. THE AZURE CONFIGURATION FILE

Configuring OpenShift Container Platform for Azure requires the /etc/azure/azure.conf file, on each node host.

If the file does not exist, create it, and add the following:

```
tenantId: <> 1
subscriptionId: <> 2
aadClientId: <> 3
aadClientSecret: <> 4
aadTenantId: <> 5
resourceGroup: <> 6
location: <> 7
```

- The AAD tenant ID for the subscription that the cluster is deployed in.
- The Azure subscription ID that the cluster is deployed in.
- The client ID for an AAD application with RBAC access to talk to Azure RM APIs.
- The client secret for an AAD application with RBAC access to talk to Azure RM APIs.
- Ensure this is the same as tenant ID (optional).
- The Azure Resource Group name that Azure VM belongs to.
- 7 The compact style Azure region, for example southeastasia (optional).

20.3. CONFIGURING MASTERS

Edit or create the master configuration file on all masters (/etc/origin/master/master-config.yaml by default) and update the contents of the apiServerArguments and controllerArguments sections:

```
kubernetesMasterConfig:
...
apiServerArguments:
    cloud-provider:
    - "azure"
    cloud-config:
    - "/etc/azure/azure.conf"
controllerArguments:
    cloud-provider:
```

- "azure"
cloud-config:
- "/etc/azure/azure.conf"

IMPORTANT

When triggering a containerized installation, only the /etc/origin and /var/lib/origin directories are mounted to the master and node container. Therefore, master-config.yaml should be in /etc/origin/master instead of /etc/.

20.4. CONFIGURING NODES

1. Edit or create the node configuration file on all nodes (/etc/origin/node/node-config.yaml by default) and update the contents of the kubeletArguments section:

kubeletArguments:
 cloud-provider:
 - "azure"
 cloud-config:
 - "/etc/azure/azure.conf"

IMPORTANT

When triggering a containerized installation, only the /etc/origin and /var/lib/origin directories are mounted to the master and node container.

Therefore, node-config.yaml should be in /etc/origin/node instead of /etc/.

2. Start or restart the OpenShift Container Platform services on the master and all nodes.

CHAPTER 21. CONFIGURING PERSISTENT STORAGE

21.1. OVERVIEW

The Kubernetes persistent volume framework allows you to provision an OpenShift Container Platform cluster with persistent storage using networked storage available in your environment. This can be done after completing the initial OpenShift Container Platform installation depending on your application needs, giving users a way to request those resources without having any knowledge of the underlying infrastructure.

These topics show how to configure persistent volumes in OpenShift Container Platform using the following supported volume plug-ins:

- NFS
- GlusterFS
- OpenStack Cinder
- Ceph RBD
- AWS Elastic Block Store (EBS)
- GCE Persistent Disk
- iSCSI
- Fibre Channel
- Azure Disk
- Azure File
- Dynamic Provisioning and Creating Storage Classes
- Volume Security
- Selector-Label Volume Binding

21.2. PERSISTENT STORAGE USING NFS

21.2.1. Overview

OpenShift Container Platform clusters can be provisioned with persistent storage using NFS. Persistent volumes (PVs) and persistent volume claims (PVCs) provide a convenient method for sharing a volume across a project. While the NFS-specific information contained in a PV definition could also be defined directly in a pod definition, doing so does not create the volume as a distinct cluster resource, making the volume more susceptible to conflicts.

This topic covers the specifics of using the NFS persistent storage type. Some familiarity with OpenShift Container Platform and NFS is beneficial. See the Persistent Storage concept topic for details on the OpenShift Container Platform persistent volume (PV) framework in general.

21.2.2. Provisioning

Storage must exist in the underlying infrastructure before it can be mounted as a volume in OpenShift Container Platform. To provision NFS volumes, a list of NFS servers and export paths are all that is required.

You must first create an object definition for the PV:

Example 21.1. PV Object Definition Using NFS

```
apiVersion: v1
kind: PersistentVolume
metadata:
   name: pv0001 1
spec:
   capacity:
    storage: 5Gi 2
accessModes:
   - ReadWriteOnce 3
nfs: 4
   path: /tmp 5
   server: 172.17.0.2 6
persistentVolumeReclaimPolicy: Recycle 7
```

- The name of the volume. This is the PV identity in various oc <command> pod commands.
- The amount of storage allocated to this volume.
- Though this appears to be related to controlling access to the volume, it is actually used similarly to labels and used to match a PVC to a PV. Currently, no access rules are enforced based on the accessModes.
- The volume type being used, in this case the **nf**s plug-in.
- The path that is exported by the NFS server.
- The host name or IP address of the NFS server.
- The reclaim policy for the PV. This defines what happens to a volume when released from its claim. Valid options are **Retain** (default) and **Recycle**. See Reclaiming Resources.

NOTE

Each NFS volume must be mountable by all schedulable nodes in the cluster.

Save the definition to a file, for example *nfs-pv.yaml*, and create the PV:

```
$ oc create -f nfs-pv.yaml
persistentvolume "pv0001" created
```

Verify that the PV was created:

```
# oc get pv
```

NAME			LABELS	CAPACITY	ACCESSMODES	STATUS
CLAIM	REASON	AGE				
pv0001			<none></none>	5368709120	RWO	Available
31s						

The next step can be to create a persistent volume claim (PVC) which will bind to the new PV:

Example 21.2. PVC Object Definition

apiVersion: v1

kind: PersistentVolumeClaim

metadata:

name: nfs-claim1

spec:

accessModes:

- ReadWriteOnce 1

resources: requests:

storage: 1Gi 2

- As mentioned above for PVs, the accessModes do not enforce security, but rather act as labels to match a PV to a PVC.
- This claim will look for PVs offering 1Gi or greater capacity.

Save the definition to a file, for example *nfs-claim.yaml*, and create the PVC:

```
# oc create -f nfs-claim.yaml
```

21.2.3. Enforcing Disk Quotas

You can use disk partitions to enforce disk quotas and size constraints. Each partition can be its own export. Each export is one PV. OpenShift Container Platform enforces unique names for PVs, but the uniqueness of the NFS volume's server and path is up to the administrator.

Enforcing quotas in this way allows the developer to request persistent storage by a specific amount (for example, 10Gi) and be matched with a corresponding volume of equal or greater capacity.

21.2.4. NFS Volume Security

This section covers NFS volume security, including matching permissions and SELinux considerations. The reader is expected to understand the basics of POSIX permissions, process UIDs, supplemental groups, and SELinux.

NOTE

See the full Volume Security topic before implementing NFS volumes.

Developers request NFS storage by referencing, in the **volumes** section of their pod definition, either a PVC by name or the NFS volume plug-in directly.

The /etc/exports file on the NFS server contains the accessible NFS directories. The target NFS directory has POSIX owner and group IDs. The OpenShift Container Platform NFS plug-in mounts the container's NFS directory with the same POSIX ownership and permissions found on the exported NFS directory. However, the container is not run with its effective UID equal to the owner of the NFS mount, which is the desired behavior.

As an example, if the target NFS directory appears on the NFS server as:

```
# ls -lZ /opt/nfs -d
drwxrws---. nfsnobody 5555 unconfined_u:object_r:usr_t:s0 /opt/nfs
# id nfsnobody
uid=65534(nfsnobody) gid=65534(nfsnobody) groups=65534(nfsnobody)
```

Then the container must match SELinux labels, and either run with a UID of **65534** (**nfsnobody** owner) or with **5555** in its supplemental groups in order to access the directory.

NOTE

The owner ID of 65534 is used as an example. Even though NFS's **root_squash** maps **root** (0) to **nfsnobody** (65534), NFS exports can have arbitrary owner IDs. Owner 65534 is not required for NFS exports.

21.2.4.1. Group IDs

The recommended way to handle NFS access (assuming it is not an option to change permissions on the NFS export) is to use supplemental groups. Supplemental groups in OpenShift Container Platform are used for shared storage, of which NFS is an example. In contrast, block storage, such as Ceph RBD or iSCSI, use the fsGroup SCC strategy and the fsGroup value in the pod's securityContext.

NOTE

It is generally preferable to use supplemental group IDs to gain access to persistent storage versus using user IDs. Supplemental groups are covered further in the full Volume Security topic.

Because the group ID on the example target NFS directory shown above is 5555, the pod can define that group ID using supplementalGroups under the pod-level securityContext definition. For example:

```
spec:
  containers:
    - name:
    ...
securityContext: 1
  supplementalGroups: [5555] 2
```

- securityContext must be defined at the pod level, not under a specific container.
- An array of GIDs defined for the pod. In this case, there is one element in the array; additional GIDs would be comma-separated.

Assuming there are no custom SCCs that might satisfy the pod's requirements, the pod will likely match the **restricted** SCC. This SCC has the **supplementalGroups** strategy set to **RunAsAny**, meaning that any supplied group ID will be accepted without range checking.

As a result, the above pod will pass admissions and will be launched. However, if group ID range checking is desired, a custom SCC, as described in pod security and custom SCCs, is the preferred solution. A custom SCC can be created such that minimum and maximum group IDs are defined, group ID range checking is enforced, and a group ID of 5555 is allowed.

NOTE

In order to use a custom SCC, you must first add it to the appropriate service account. For example, use the default service account in the given project unless another has been specified on the pod specification. See Add an SCC to a User, Group, or Project for details.

21.2.4.2. User IDs

User IDs can be defined in the container image or in the pod definition. The full Volume Security topic covers controlling storage access based on user IDs, and should be read prior to setting up NFS persistent storage.

NOTE

It is generally preferable to use supplemental group IDs to gain access to persistent storage versus using user IDs.

In the example target NFS directory shown above, the container needs its UID set to 65534 (ignoring group IDs for the moment), so the following can be added to the pod definition:

```
spec:
containers: 1
- name:
...
securityContext:
runAsUser: 65534 2
```

- Pods contain a securtityContext specific to each container (shown here) and a pod-level securityContext which applies to all containers defined in the pod.
- 65534 is the **nfsnobody** user.

Assuming the **default** project and the **restricted** SCC, the pod's requested user ID of 65534 will, unfortunately, not be allowed, and therefore the pod will fail. The pod fails because of the following:

- It requests 65534 as its user ID.
- All SCCs available to the pod are examined to see which SCC will allow a user ID of 65534 (actually, all policies of the SCCs are checked but the focus here is on user ID).
- Because all available SCCs use MustRunAsRange for their runAsUser strategy, UID range checking is required.

• 65534 is not included in the SCC or project's user ID range.

It is generally considered a good practice not to modify the predefined SCCs. The preferred way to fix this situation is to create a custom SCC, as described in the full Volume Security topic. A custom SCC can be created such that minimum and maximum user IDs are defined, UID range checking is still enforced, and the UID of 65534 will be allowed.

NOTE

In order to use a custom SCC, you must first add it to the appropriate service account. For example, use the default service account in the given project unless another has been specified on the pod specification. See Add an SCC to a User, Group, or Project for details.

21.2.4.3. SELinux

NOTE

See the full Volume Security topic for information on controlling storage access in conjunction with using SELinux.

By default, SELinux does not allow writing from a pod to a remote NFS server. The NFS volume mounts correctly, but is read-only.

To enable writing to NFS volumes with SELinux enforcing on each node, run:

```
# setsebool -P virt_use_nfs 1
```

The -P option above makes the bool persistent between reboots.

The **virt_use_nfs** boolean is defined by the **docker-selinux** package. If an error is seen indicating that this bool is not defined, ensure this package has been installed.

21.2.4.4. Export Settings

In order to enable arbitrary container users to read and write the volume, each exported volume on the NFS server should conform to the following conditions:

• Each export must be:

```
/<example_fs> *(rw,root_squash)
```

- The firewall must be configured to allow traffic to the mount point.
 - For NFSv4, configure the default port 2049 (nfs) and port 111 (portmapper).

NFSv4

```
# iptables -I INPUT 1 -p tcp --dport 2049 -j ACCEPT
# iptables -I INPUT 1 -p tcp --dport 111 -j ACCEPT
```

For NFSv3, there are three ports to configure: 2049 (nfs), 20048 (mountd), and 111 (portmapper).

NFSv3

```
# iptables -I INPUT 1 -p tcp --dport 2049 -j ACCEPT
# iptables -I INPUT 1 -p tcp --dport 20048 -j ACCEPT
# iptables -I INPUT 1 -p tcp --dport 111 -j ACCEPT
```

The NFS export and directory must be set up so that it is accessible by the target pods. Either
set the export to be owned by the container's primary UID, or supply the pod group access
using supplementalGroups, as shown in Group IDs above. See the full Volume Security topic
for additional pod security information as well.

21.2.5. Reclaiming Resources

NFS implements the OpenShift Container Platform **Recyclable** plug-in interface. Automatic processes handle reclamation tasks based on policies set on each persistent volume.

By default, persistent volumes are set to **Retain**. NFS volumes which are set to **Recycle** are scrubbed (i.e., rm -rf is run on the volume) after being released from their claim (i.e, after the user's **PersistentVolumeClaim** bound to the volume is deleted). Once recycled, the NFS volume can be bound to a new claim.

21.2.6. Automation

Clusters can be provisioned with persistent storage using NFS in the following ways:

- Enforce storage quotas using disk partitions.
- Enforce security by restricting volumes to the project that has a claim to them.
- Configure reclamation of discarded resources for each PV.

They are many ways that you can use scripts to automate the above tasks. You can use an example Ansible playbook to help you get started.

21.2.7. Additional Configuration and Troubleshooting

Depending on what version of NFS is being used and how it is configured, there may be additional configuration steps needed for proper export and security mapping. The following are some that may apply:

NFSv4 mount incorrectly shows all files with ownership of nobody:nobody	 Could be attributed to the ID mapping settings (/etc/idmapd.conf) on your NFS See this Red Hat Solution.
Disabling ID mapping on NFSv4	On both the NFS client and server, run: # echo 'Y' > /sys/module/nfsd/parameters/nfs4_disable _idmapping

21.3. PERSISTENT STORAGE USING GLUSTERFS

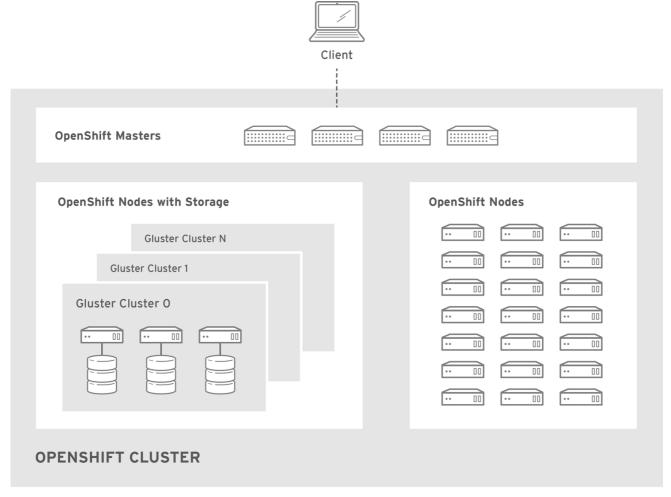

21.3.1. Overview

You can configure your OpenShift Container Platform cluster to use Red Hat Gluster Storage as persistent storage for containerized applications. There are two deployment solutions available when using Red Hat Gluster Storage, using either a containerized or dedicated storage cluster. This topic focuses mainly on the the persistent volume plug-in solution using a dedicated Red Hat Gluster Storage cluster.

21.3.1.1. Containerized Red Hat Gluster Storage

Starting with the Red Hat Gluster Storage 3.1 update 3 release, you can deploy containerized Red Hat Gluster Storage directly on OpenShift Container Platform. Containerized Red Hat Gluster Storage converged with OpenShift Container Platform addresses the use case where containerized applications require both shared file storage and the flexibility of a converged infrastructure with compute and storage instances being scheduled and run from the same set of hardware.

Figure 21.1. Architecture - Red Hat Gluster Storage Container Converged with OpenShift

OPENSHIFT_412816_0716

Step-by-step instructions for this containerized solution are provided separately in the following Red Hat Gluster Storage documentation:

Container-Native Storage for OpenShift Container Platform

21.3.1.2. Container Native Storage Recommendations

OpenShift Container Platform offers container native storage (CNS) storage, which makes it easier for OpenShift Container Platform users to fulfill their storage needs. With CNS, solution users and administrators are empowered to have storage and application pods running together on the same infrastructure and sharing the same resources.

Follow the Container Native Storage with GlusterFS guidance for configuring CNS as part of a OpenShift Container Platform cluster.

Currently, up to 100 CNS volumes on one trusted storage pool (TSP) is supported.

21.3.1.2.1. Creation Time of Volumes with Container Native Storage

Building environment storage can influence the time it takes for an application to start. For example, if the application pod requires a persistent volume claim (PVC), then extra time might have to be considered for CNS to be created and bound to the corresponding PVC. This effects the build time for an application pod to start.

Creation time of CNS volumes scales linearly up to 100 volumes. In the latest tests, each volume took approximately 6 seconds to be created, allocated, and bound to a pod.

All tests were performed on one trusted storage pool (TSP), using hardware configuration for CNS per the Container Native Storage with GlusterFS guidance.

Dynamic storage provisioning and storage classes were also configured and used when provisioning the PVC.

21.3.1.2.2. Deletion Time of Volumes with Container Native Storage

When you delete a PVC that is used by an application pod, then that action will trigger the deletion of the CNS volume that was used by the PVC.

PVCs will disappear immediately from the oc get pvc output. However, the time to delete and recycle CNS volumes depends on the number of CNS volumes. In the latest tests, the deletion time of CNS volumes proved to scale linearly up to 100 volumes.

NOTE

Deletion time does not affect application users. CNS deletion behavior serves as orientation for CNS storage administrators to be able to estimate how long it will approximately take for CNS volumes to be removed from a CNS cluster.

21.3.1.2.3. Recommended Memory Requirements for Container Native Storage

The recommended memory requirements are 32 GB per OpenShift Container Platform node hosting CNS pods.

IMPORTANT

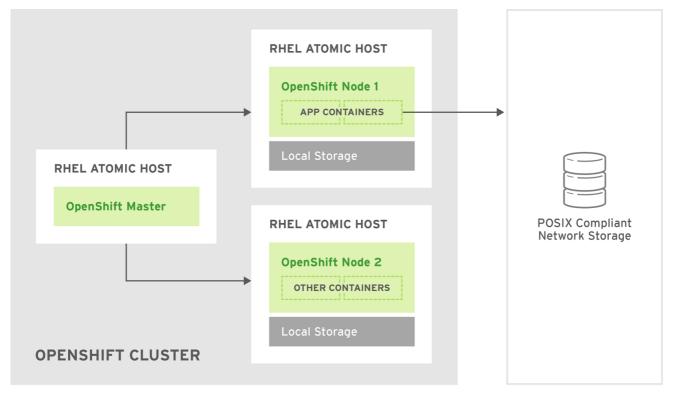

Follow the planning guidelines when planning hardware for a CNS storage environment to ensure that you have enough memory.

21.3.1.3. Dedicated Storage Cluster

If you have a dedicated Red Hat Gluster Storage cluster available in your environment, you can configure OpenShift Container Platform's Gluster volume plug-in. The dedicated storage cluster

delivers persistent Red Hat Gluster Storage file storage for containerized applications over the network. The applications access storage served out from the storage clusters through common storage protocols.

Figure 21.2. Architecture - Dedicated Red Hat Gluster Storage Cluster Using the OpenShift Container Platform Volume Plug-in

OPENSHIFT_412816_0716

You can also dynamically provision volumes in a dedicated Red Hat Gluster Storage cluster that are enabled by Heketi. See Managing Volumes Using Heketi in the Red Hat Gluster Storage Administration Guide for more information.

This solution is a conventional deployment where containerized compute applications run on an OpenShift Container Platform cluster. The remaining sections in this topic provide the step-by-step instructions for the dedicated Red Hat Gluster Storage solution.

This topic presumes some familiarity with OpenShift Container Platform and GlusterFS:

- See the Persistent Storage topic for details on the OpenShift Container Platform PV framework in general.
- See the Red Hat Gluster Storage 3 Administration Guide for more on GlusterFS.

IMPORTANT

High-availability of storage in the infrastructure is left to the underlying storage provider.

21.3.2. Support Requirements

The following requirements must be met to create a supported integration of Red Hat Gluster Storage and OpenShift Container Platform.

21.3.2.1. Supported Operating Systems

The following table lists the supported versions of OpenShift Container Platform with Red Hat Gluster Storage Server.

Red Hat Gluster Storage	OpenShift Container Platform
3.1.3	3.1 or later

21.3.2.2. Environment Requirements

The environment requirements for OpenShift Container Platform and Red Hat Gluster Storage are described in this section.

Red Hat Gluster Storage

- All installations of Red Hat Gluster Storage must have valid subscriptions to Red Hat Network channels and Subscription Management repositories.
- Red Hat Gluster Storage installations must adhere to the requirements laid out in the Red Hat Gluster Storage Installation Guide.
- Red Hat Gluster Storage installations must be completely up to date with the latest patches and upgrades. Refer to the Red Hat Gluster Storage 3.1 Installation Guide to upgrade to the latest version.
- The versions of OpenShift Container Platform and Red Hat Gluster Storage integrated must be compatible, according to the information in Supported Operating Systems.
- A fully-qualified domain name (FQDN) must be set for each hypervisor and Red Hat Gluster Storage server node. Ensure that correct DNS records exist, and that the FQDN is resolvable via both forward and reverse DNS lookup.

Red Hat OpenShift Container Platform

- All installations of OpenShift Container Platform must have valid subscriptions to Red Hat Network channels and Subscription Management repositories.
- OpenShift Container Platform installations must adhere to the requirements laid out in the Installation and Configuration documentation.
- The OpenShift Container Platform cluster must be up and running.
- A user with **cluster-admin** permissions must be created.
- All OpenShift Container Platform nodes on RHEL systems must have the glusterfs-fuse RPM installed, which should match the version of Red Hat Gluster Storage server running in the containers. For more information on installing glusterfs-fuse, see Native Client in the Red Hat Gluster Storage Administration Guide.

21.3.3. Provisioning

To provision GlusterFS volumes using the dedicated storage cluster solution, the following are required:

- An existing storage device in your underlying infrastructure.
- A distinct list of servers (IP addresses) in the Gluster cluster, to be defined as endpoints.
- A service, to persist the endpoints (optional).
- An existing Gluster volume to be referenced in the persistent volume object.
- **glusterfs-fuse** installed on each schedulable OpenShift Container Platform node in your cluster:

\$ yum install glusterfs-fuse

NOTE

Persistent volumes (PVs) and persistent volume claims (PVCs) can share volumes across a single project. While the GlusterFS-specific information contained in a PV definition could also be defined directly in a pod definition, doing so does not create the volume as a distinct cluster resource, making the volume more susceptible to conflicts.

21.3.3.1. Creating Gluster Endpoints

An endpoints definition defines the GlusterFS cluster as **EndPoints** and includes the IP addresses of your Gluster servers. The port value can be any numeric value within the accepted range of ports. Optionally, you can create a service that persists the endpoints.

1. Define the following service:

```
apiVersion: v1
kind: Service
metadata:
   name: glusterfs-cluster 1
spec:
   ports:
   - port: 1
```

- This name must be defined in the endpoints definition. If using a service, then the endpoints name must match the service name.
- 2. Save the service definition to a file, for example *gluster-service.yaml*, then create the service:

```
$ oc create -f gluster-service.yaml
```

3. Verify that the service was created:

4. Define the Gluster endpoints:

```
apiVersion: v1
kind: Endpoints
metadata:
   name: glusterfs-cluster 1
subsets:
   - addresses:
    - ip: 192.168.122.221 2
   ports:
    - port: 1
   - addresses:
    - ip: 192.168.122.222 3
   ports:
    - port: 1
```

- This name must match the service name from step 1.
- The ip values must be the actual IP addresses of a Gluster server, not fully-qualified host names.
- The port number is ignored.
- 5. Save the endpoints definition to a file, for example *gluster-endpoints.yaml*, then create the endpoints:

```
$ oc create -f gluster-endpoints.yaml
endpoints "glusterfs-cluster" created
```

6. Verify that the endpoints were created:

```
      $ oc get endpoints

      NAME
      ENDPOINTS
      AGE

      docker-registry
      10.1.0.3:5000
      4h

      glusterfs-cluster
      192.168.122.221:1,192.168.122.222:1
      11s

      kubernetes
      172.16.35.3:8443
      4d
```

21.3.3.2. Creating the Persistent Volume

NOTE

GlusterFS does not support the 'Recycle' reclaim policy.

1. Next, define the PV in an object definition before creating it in OpenShift Container Platform:

```
apiVersion: v1
kind: PersistentVolume
metadata:
   name: gluster-default-volume 1
spec:
   capacity:
    storage: 2Gi 2
   accessModes: 3
    - ReadWriteMany
```

glusterfs: 4

endpoints: glusterfs-cluster 5

path: myVol1 6
readOnly: false

persistentVolumeReclaimPolicy: Retain 7

- The name of the volume. This is how it is identified via persistent volume claims or from pods.
- The amount of storage allocated to this volume.
- accessModes are used as labels to match a PV and a PVC. They currently do not define any form of access control.
- The volume type being used, in this case the glusterfs plug-in.
- The endpoints name that defines the Gluster cluster created in Creating Gluster Endpoints.
- The Gluster volume that will be accessed, as shown in the gluster volume status command.
- 7 The volume reclaim policy Retain indicates that the volume will be preserved after the pods accessing it terminates. For GlusterFS, the accepted values include Retain, and Delete.

NOTE

Endpoints are name-spaced. Each project accessing the Gluster volume needs its own endpoints.

1. Save the definition to a file, for example *gluster-pv.yaml*, and create the persistent volume:

```
$ oc create -f gluster-pv.yaml
```

2. Verify that the persistent volume was created:

```
$ oc get pv

NAME LABELS CAPACITY ACCESSMODES

STATUS CLAIM REASON AGE

gluster-default-volume <none> 2147483648 RWX

Available 2s
```

21.3.3.3. Creating the Persistent Volume Claim

Developers request GlusterFS storage by referencing either a PVC or the Gluster volume plug-in directly in the **volumes** section of a pod spec. A PVC exists only in the user's project and can only be referenced by pods within that project. Any attempt to access a PV across a project causes the pod to fail.

1. Create a PVC that will bind to the new PV:

```
apiVersion: v1
```

```
kind: PersistentVolumeClaim
metadata:
   name: gluster-claim
spec:
   accessModes:
   - ReadWriteMany 1
   resources:
     requests:
     storage: 1Gi 2
```

- accessModes do not enforce security, but rather act as labels to match a PV to a PVC.
- This claim will look for PVs offering 1Gi or greater capacity.
- 2. Save the definition to a file, for example *gluster-claim.yaml*, and create the PVC:

```
$ oc create -f gluster-claim.yaml
```

NOTE

PVs and PVCs make sharing a volume across a project simpler. The gluster-specific information contained in the PV definition can also be defined directly in a pod specification.

21.3.4. Gluster Volume Security

This section covers Gluster volume security, including matching permissions and SELinux considerations. Understanding the basics of POSIX permissions, process UIDs, supplemental groups, and SELinux is presumed.

NOTE

See the full Volume Security topic before implementing Gluster volumes.

As an example, assume that the target Gluster volume, **HadoopVol** is mounted under **/mnt/glusterfs/**, with the following POSIX permissions and SELinux labels:

In order to access the <code>HadoopVol</code> volume, containers must match the SELinux label, and run with a UID of 592 or 590 in their supplemental groups. The OpenShift Container Platform GlusterFS plug-in mounts the volume in the container with the same POSIX ownership and permissions found on the target gluster mount, namely the owner will be <code>592</code> and group ID will be <code>590</code>. However, the container is not run with its effective UID equal to <code>592</code>, nor with its GID equal to <code>590</code>, which is the desired behavior. Instead, a container's UID and supplemental groups are determined by Security Context Constraints (SCCs) and the project defaults.

21.3.4.1. Group IDs

Configure Gluster volume access by using supplemental groups, assuming it is not an option to change permissions on the Gluster mount. Supplemental groups in OpenShift Container Platform are used for shared storage, such as GlusterFS. In contrast, block storage, such as Ceph RBD or iSCSI, use the fsGroup SCC strategy and the fsGroup value in the pod's securityContext.

NOTE

Use supplemental group IDs instead of user IDs to gain access to persistent storage. Supplemental groups are covered further in the full Volume Security topic.

The group ID on the target Gluster mount example above is 590. Therefore, a pod can define that group ID using supplementalGroups under the pod-level securityContext definition. For example:

```
spec:
   containers:
    - name:
    ...
securityContext: 1
   supplementalGroups: [590] 2
```

- securityContext must be defined at the pod level, not under a specific container.
- An array of GIDs defined at the pod level.

Assuming there are no custom SCCs that satisfy the pod's requirements, the pod matches the **restricted** SCC. This SCC has the **supplementalGroups** strategy set to **RunAsAny**, meaning that any supplied group IDs are accepted without range checking.

As a result, the above pod will pass admissions and can be launched. However, if group ID range checking is desired, use a custom SCC, as described in pod security and custom SCCs. A custom SCC can be created to define minimum and maximum group IDs, enforce group ID range checking, and allow a group ID of **590**.

21.3.4.2. User IDs

User IDs can be defined in the container image or in the pod definition. The full Volume Security topic covers controlling storage access based on user IDs, and should be read prior to setting up NFS persistent storage.

NOTE

Use supplemental group IDs instead of user IDs to gain access to persistent storage.

In the target Gluster mount example above, the container needs a UID set to **592**, so the following can be added to the pod definition:

```
spec:
  containers: 1
  name:
```

. . .

securityContext:

runAsUser: 592 2

Pods contain a securtityContext specific to each container and a pod-level securityContext, which applies to all containers defined in the pod.

The UID defined on the Gluster mount.

With the **default** project and the **restricted** SCC, a pod's requested user ID of **592** will not be allowed, and the pod will fail. This is because:

- The pod requests 592 as its user ID.
- All SCCs available to the pod are examined to see which SCC will allow a user ID of 592.
- Because all available SCCs use MustRunAsRange for their runAsUser strategy, UID range checking is required.
- 592 is not included in the SCC or project's user ID range.

Do not modify the predefined SCCs. Insead, create a custom SCC so that minimum and maximum user IDs are defined, UID range checking is still enforced, and the UID of **592** will be allowed.

21.3.4.3. SELinux

NOTE

See the full Volume Security topic for information on controlling storage access in conjunction with using SELinux.

By default, SELinux does not allow writing from a pod to a remote Gluster server.

To enable writing to GlusterFS volumes with SELinux enforcing on each node, run:

\$ sudo setsebool -P virt_sandbox_use_fusefs on

NOTE

The virt_sandbox_use_fusefs boolean is defined by the docker-selinux package. If you get an error saying it is not defined, please ensure that this package is installed.

The -P option makes the bool persistent between reboots.

21.4. PERSISTENT STORAGE USING OPENSTACK CINDER

21.4.1. Overview

You can provision your OpenShift Container Platform cluster with persistent storage using OpenStack Cinder. Some familiarity with Kubernetes and OpenStack is assumed.

Before creating persistent volumes using Cinder, OpenShift Container Platform must first be properly configured for OpenStack.

The Kubernetes persistent volume framework allows administrators to provision a cluster with persistent storage and gives users a way to request those resources without having any knowledge of the underlying infrastructure. OpenStack Cinder volumes can be provisioned dynamically. Persistent volumes are not bound to a single project or namespace; they can be shared across the OpenShift Container Platform cluster. Persistent volume claims, however, are specific to a project or namespace and can be requested by users.

For a detailed example, see the guide for WordPress and MySQL using persistent volumes.

IMPORTANT

High-availability of storage in the infrastructure is left to the underlying storage provider.

21.4.2. Provisioning

Storage must exist in the underlying infrastructure before it can be mounted as a volume in OpenShift Container Platform. After ensuring OpenShift Container Platform is configured for OpenStack, all that is required for Cinder is a Cinder volume ID and the PersistentVolume API.

21.4.2.1. Creating the Persistent Volume

NOTE

Cinder does not support the 'Recycle' reclaim policy.

You must define your persistent volume in an object definition before creating it in OpenShift Container Platform:

Example 21.3. Persistent Volume Object Definition Using Cinder

```
apiVersion: "v1"
kind: "PersistentVolume"
metadata:
   name: "pv0001" 1
spec:
   capacity:
    storage: "5Gi" 2
   accessModes:
    - "ReadWriteOnce"
   cinder: 3
    fsType: "ext3" 4
   volumeID: "f37a03aa-6212-4c62-a805-9ce139fab180" 5
```

The name of the volume. This will be how it is identified via persistent volume claims or from pods.

- The amount of storage allocated to this volume.
- This defines the volume type being used, in this case the **cinder** plug-in.
- File system type to mount.
- This is the Cinder volume that will be used.

Changing the value of the **fstype** parameter after the volume has been formatted and provisioned can result in data loss and pod failure.

Save your definition to a file, for example *cinder-pv.yaml*, and create the persistent volume:

```
# oc create -f cinder-pv.yaml
persistentvolume "pv0001" created
```

Verify that the persistent volume was created:

```
# oc get pv
NAME LABELS CAPACITY ACCESSMODES STATUS CLAIM REASON
AGE
pv0001 <none> 5Gi RWO Available
2s
```

Users can then request storage using persistent volume claims, which can now utilize your new persistent volume.

IMPORTANT

Persistent volume claims only exist in the user's namespace and can only be referenced by a pod within that same namespace. Any attempt to access a persistent volume from a different namespace causes the pod to fail.

21.4.2.2. Volume Format

Before OpenShift Container Platform mounts the volume and passes it to a container, it checks that it contains a file system as specified by the **fsType** parameter in the persistent volume definition. If the device is not formatted with the file system, all data from the device is erased and the device is automatically formatted with the given file system.

This allows using unformatted Cinder volumes as persistent volumes, because OpenShift Container Platform formats them before the first use.

21.5. PERSISTENT STORAGE USING CEPH RADOS BLOCK DEVICE (RBD)

21.5.1. Overview

OpenShift Container Platform clusters can be provisioned with persistent storage using Ceph RBD.

Persistent volumes (PVs) and persistent volume claims (PVCs) can share volumes across a single project. While the Ceph RBD-specific information contained in a PV definition could also be defined directly in a pod definition, doing so does not create the volume as a distinct cluster resource, making the volume more susceptible to conflicts.

This topic presumes some familiarity with OpenShift Container Platform and Ceph RBD. See the Persistent Storage concept topic for details on the OpenShift Container Platform persistent volume (PV) framework in general.

NOTE

Project and *namespace* are used interchangeably throughout this document. See Projects and Users for details on the relationship.

IMPORTANT

High-availability of storage in the infrastructure is left to the underlying storage provider.

21.5.2. Provisioning

To provision Ceph volumes, the following are required:

- An existing storage device in your underlying infrastructure.
- The Ceph key to be used in an OpenShift Container Platform secret object.
- The Ceph image name.
- The file system type on top of the block storage (e.g., ext4).
- **ceph-common** installed on each schedulable OpenShift Container Platform node in your cluster:

yum install ceph-common

21.5.2.1. Creating the Ceph Secret

Define the authorization key in a secret configuration, which is then converted to base64 for use by OpenShift Container Platform.

NOTE

In order to use Ceph storage to back a persistent volume, the secret must be created in the same project as the PVC and pod. The secret cannot simply be in the default project.

 Run ceph auth get-key on a Ceph MON node to display the key value for the client.admin user:

apiVersion: v1 kind: Secret metadata: name: ceph-secret

data:

key: QVFB0FF2SlZheUJQRVJBQWgvS2cwT1laQUhPQno3akZwekxxdGc9PQ==

2. Save the secret definition to a file, for example ceph-secret.yaml, then create the secret:

```
$ oc create -f ceph-secret.yaml
```

3. Verify that the secret was created:

```
# oc get secret ceph-secret
NAME TYPE DATA AGE
ceph-secret Opaque 1 23d
```

21.5.2.2. Creating the Persistent Volume

NOTE

Ceph RBD does not support the 'Recycle' reclaim policy.

Developers request Ceph RBD storage by referencing either a PVC, or the Gluster volume plug-in directly in the **volumes** section of a pod specification. A PVC exists only in the user's namespace and can be referenced only by pods within that same namespace. Any attempt to access a PV from a different namespace causes the pod to fail.

1. Define the PV in an object definition before creating it in OpenShift Container Platform:

Example 21.4. Persistent Volume Object Definition Using Ceph RBD

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: ceph-pv 1
spec:
  capacity:
    storage: 2Gi 2
  accessModes:
    - ReadWriteOnce 3
  rbd: 4
    monitors: 5
      - 192.168.122.133:6789
    pool: rbd
    image: ceph-image
    user: admin
    secretRef:
      name: ceph-secret 6
    fsType: ext4 7
    readOnly: false
  persistentVolumeReclaimPolicy: Retain
```

The name of the PV that is referenced in pod definitions or displayed in various oc volume commands.

- The amount of storage allocated to this volume.
- accessModes are used as labels to match a PV and a PVC. They currently do not define any form of access control. All block storage is defined to be single user (nonshared storage).
- The volume type being used, in this case the **rbd** plug-in.
- An array of Ceph monitor IP addresses and ports.
- The Ceph secret used to create a secure connection from OpenShift Container Platform to the Ceph server.
- The file system type mounted on the Ceph RBD block device.

Changing the value of the fstype parameter after the volume has been formatted and provisioned can result in data loss and pod failure.

2. Save your definition to a file, for example *ceph-pv.yaml*, and create the PV:

```
# oc create -f ceph-pv.yaml
```

3. Verify that the persistent volume was created:

```
# oc get pv
NAME LABELS CAPACITY ACCESSMODES
STATUS CLAIM REASON AGE
ceph-pv < none> 2147483648 RWO
Available 2s
```

4. Create a PVC that will bind to the new PV:

Example 21.5. PVC Object Definition

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
   name: ceph-claim
spec:
   accessModes: 1
   - ReadWriteOnce
   resources:
    requests:
    storage: 2Gi 2
```

- The accessModes do not enforce access right, but instead act as labels to match a PV to a PVC.
- 2 This claim looks for PVs offering **2Gi** or greater capacity.

5. Save the definition to a file, for example ceph-claim.yaml, and create the PVC:

```
# oc create -f ceph-claim.yaml
```

21.5.3. Ceph Volume Security

NOTE

See the full Volume Security topic before implementing Ceph RBD volumes.

A significant difference between shared volumes (NFS and GlusterFS) and block volumes (Ceph RBD, iSCSI, and most cloud storage), is that the user and group IDs defined in the pod definition or container image are applied to the target physical storage. This is referred to as managing ownership of the block device. For example, if the Ceph RBD mount has its owner set to 123 and its group ID set to 567, and if the pod defines its runAsUser set to 222 and its fsGroup to be 7777, then the Ceph RBD physical mount's ownership will be changed to 222:7777.

NOTE

Even if the user and group IDs are not defined in the pod specification, the resulting pod may have defaults defined for these IDs based on its matching SCC, or its project. See the full Volume Security topic which covers storage aspects of SCCs and defaults in greater detail.

A pod defines the group ownership of a Ceph RBD volume using the **fsGroup** stanza under the pod's **securityContext** definition:

```
spec:
   containers:
        - name:
        ...
securityContext: 1
   fsGroup: 7777 2
```

- The securityContext must be defined at the pod level, not under a specific container.
- All containers in the pod will have the same fsGroup ID.

21.6. PERSISTENT STORAGE USING AWS ELASTIC BLOCK STORE

21.6.1. Overview

OpenShift Container Platform supports AWS Elastic Block Store volumes (EBS). You can provision your OpenShift Container Platform cluster with persistent storage using AWS EC2. Some familiarity with Kubernetes and AWS is assumed.

Before creating persistent volumes using AWS, OpenShift Container Platform must first be properly configured for AWS ElasticBlockStore.

The Kubernetes persistent volume framework allows administrators to provision a cluster with persistent storage and gives users a way to request those resources without having any knowledge of the underlying infrastructure. AWS Elastic Block Store volumes can be provisioned dynamically. Persistent volumes are not bound to a single project or namespace; they can be shared across the OpenShift Container Platform cluster. Persistent volume claims, however, are specific to a project or namespace and can be requested by users.

IMPORTANT

High-availability of storage in the infrastructure is left to the underlying storage provider.

21.6.2. Provisioning

Storage must exist in the underlying infrastructure before it can be mounted as a volume in OpenShift Container Platform. After ensuring OpenShift is configured for AWS Elastic Block Store, all that is required for OpenShift and AWS is an AWS EBS volume ID and the PersistentVolume API.

21.6.2.1. Creating the Persistent Volume

NOTE

AWS does not support the 'Recycle' reclaim policy.

You must define your persistent volume in an object definition before creating it in OpenShift Container Platform:

Example 21.6. Persistent Volume Object Definition Using AWS

```
apiVersion: "v1"
kind: "PersistentVolume"
metadata:
   name: "pv0001" 1
spec:
   capacity:
    storage: "5Gi" 2
   accessModes:
        - "ReadWriteOnce"
   awsElasticBlockStore: 3
        fsType: "ext4" 4
        volumeID: "vol-f37a03aa" 5
```

- The name of the volume. This will be how it is identified via persistent volume claims or from pods.
- The amount of storage allocated to this volume.

- This defines the volume type being used, in this case the awsElasticBlockStore plug-in.
- 4 File system type to mount.
- This is the AWS volume that will be used.

Changing the value of the fstype parameter after the volume has been formatted and provisioned can result in data loss and pod failure.

Save your definition to a file, for example aws-pv.yaml, and create the persistent volume:

```
# oc create -f aws-pv.yaml
persistentvolume "pv0001" created
```

Verify that the persistent volume was created:

```
# oc get pv
NAME LABELS CAPACITY ACCESSMODES STATUS CLAIM REASON
AGE
pv0001 <none> 5Gi RWO Available
2s
```

Users can then request storage using persistent volume claims, which can now utilize your new persistent volume.

IMPORTANT

Persistent volume claims only exist in the user's namespace and can only be referenced by a pod within that same namespace. Any attempt to access a persistent volume from a different namespace causes the pod to fail.

21.6.2.2. Volume Format

Before OpenShift Container Platform mounts the volume and passes it to a container, it checks that it contains a file system as specified by the fsType parameter in the persistent volume definition. If the device is not formatted with the file system, all data from the device is erased and the device is automatically formatted with the given file system.

This allows using unformatted AWS volumes as persistent volumes, because OpenShift Container Platform formats them before the first use.

21.7. PERSISTENT STORAGE USING GCE PERSISTENT DISK

21.7.1. Overview

OpenShift Container Platform supports GCE Persistent Disk volumes (gcePD). You can provision your OpenShift Container Platform cluster with persistent storage using GCE. Some familiarity with Kubernetes and GCE is assumed.

Before creating persistent volumes using GCE, OpenShift Container Platform must first be properly configured for GCE Persistent Disk.

The Kubernetes persistent volume framework allows administrators to provision a cluster with persistent storage and gives users a way to request those resources without having any knowledge of the underlying infrastructure. GCE Persistent Disk volumes can be provisioned dynamically. Persistent volumes are not bound to a single project or namespace; they can be shared across the OpenShift Container Platform cluster. Persistent volume claims, however, are specific to a project or namespace and can be requested by users.

IMPORTANT

High-availability of storage in the infrastructure is left to the underlying storage provider.

21.7.2. Provisioning

Storage must exist in the underlying infrastructure before it can be mounted as a volume in OpenShift Container Platform. After ensuring OpenShift Container Platform is configured for GCE PersistentDisk, all that is required for OpenShift Container Platform and GCE is an GCE Persistent Disk volume ID and the PersistentVolume API.

21.7.2.1. Creating the Persistent Volume

NOTE

GCE does not support the 'Recycle' reclaim policy.

You must define your persistent volume in an object definition before creating it in OpenShift Container Platform:

Example 21.7. Persistent Volume Object Definition Using GCE

```
apiVersion: "v1"
kind: "PersistentVolume"
metadata:
   name: "pv0001" 1
spec:
   capacity:
    storage: "5Gi" 2
accessModes:
    - "ReadWriteOnce"
gcePersistentDisk: 3
   fsType: "ext4" 4
   pdName: "pd-disk-1" 5
```

- The name of the volume. This will be how it is identified via persistent volume claims or from pods.
- The amount of storage allocated to this volume.

- This defines the volume type being used, in this case the gcePersistentDisk plug-in.
- File system type to mount.
- This is the GCE Persistent Disk volume that will be used.

Changing the value of the fstype parameter after the volume has been formatted and provisioned can result in data loss and pod failure.

Save your definition to a file, for example *gce-pv.yaml*, and create the persistent volume:

```
# oc create -f gce-pv.yaml
persistentvolume "pv0001" created
```

Verify that the persistent volume was created:

```
# oc get pv
NAME LABELS CAPACITY ACCESSMODES STATUS CLAIM REASON
AGE
pv0001 <none> 5Gi RWO Available
2s
```

Users can then request storage using persistent volume claims, which can now utilize your new persistent volume.

IMPORTANT

Persistent volume claims only exist in the user's namespace and can only be referenced by a pod within that same namespace. Any attempt to access a persistent volume from a different namespace causes the pod to fail.

21.7.2.2. Volume Format

Before OpenShift Container Platform mounts the volume and passes it to a container, it checks that it contains a file system as specified by the **fsType** parameter in the persistent volume definition. If the device is not formatted with the file system, all data from the device is erased and the device is automatically formatted with the given file system.

This allows using unformatted GCE volumes as persistent volumes, because OpenShift Container Platform formats them before the first use.

21.7.2.3. Multi-zone Configuration

In multi-zone configurations, You must specify failure-domain.beta.kubernetes.io/region and failure-domain.beta.kubernetes.io/zone PV labels to match the zone where GCE volume exists.

Example 21.8. Persistent Volume Object With Failure Domain

```
apiVersion: "v1"
kind: "PersistentVolume"
metadata:
  name: "pv0001"
  labels:
    failure-domain.beta.kubernetes.io/region: "us-central1" 1
    failure-domain.beta.kubernetes.io/zone: "us-central1-a" 2
  capacity:
    storage: "5Gi"
  accessModes:
    - "ReadWriteOnce"
  qcePersistentDisk:
    fsType: "ext4"
    pdName: "pd-disk-1"
```

- The region in which the volume exists.
- The zone in which the volume exists.

21.8. PERSISTENT STORAGE USING ISCSI

21.8.1. Overview

You can provision your OpenShift Container Platform cluster with persistent storage using iSCSI. Some familiarity with Kubernetes and iSCSI is assumed.

The Kubernetes persistent volume framework allows administrators to provision a cluster with persistent storage and gives users a way to request those resources without having any knowledge of the underlying infrastructure.

IMPORTANT

High-availability of storage in the infrastructure is left to the underlying storage provider.

21.8.2. Provisioning

Verify that the storage exists in the underlying infrastructure before mounting it as a volume in OpenShift Container Platform. All that is required for the iSCSI is the iSCSI target portal, a valid iSCSI Qualified Name (IQN), a valid LUN number, the filesystem type, and the PersistentVolume API.

Optionally, multipath portals and Challenge Handshake Authentication Protocol (CHAP) configuration can be provided.

NOTE

iSCSI does not support the 'Recycle' reclaim policy.

Example 21.9. Persistent Volume Object Definition

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: iscsi-pv
spec:
  capacity:
    storage: 1Gi
  accessModes:

    ReadWriteOnce

  iscsi:
     targetPortal: 10.16.154.81
     ign: ign.2014-12.example.server:storage.target00
     lun: 0
     fsType: 'ext4'
     readOnly: false
     chapAuthDiscovery: true
        chapAuthSession: true
        secretRef:
           name: chap-secret
```

21.8.2.1. Enforcing Disk Quotas

Use LUN partitions to enforce disk quotas and size constraints. Each LUN is one persistent volume. Kubernetes enforces unique names for persistent volumes.

Enforcing quotas in this way allows the end user to request persistent storage by a specific amount (e.g., 10Gi) and be matched with a corresponding volume of equal or greater capacity.

21.8.2.2. iSCSI Volume Security

Users request storage with a PersistentVolumeClaim. This claim only lives in the user's namespace and can only be referenced by a pod within that same namespace. Any attempt to access a persistent volume across a namespace causes the pod to fail.

Each iSCSI LUN must be accessible by all nodes in the cluster.

21.9. PERSISTENT STORAGE USING FIBRE CHANNEL

21.9.1. Overview

You can provision your OpenShift Container Platform cluster with persistent storage using Fibre Channel. Some familiarity with Kubernetes and Fibre Channel is assumed.

The Kubernetes persistent volume framework allows administrators to provision a cluster with persistent storage and gives users a way to request those resources without having any knowledge of the underlying infrastructure.

IMPORTANT

High-availability of storage in the infrastructure is left to the underlying storage provider.

21.9.2. Provisioning

Storage must exist in the underlying infrastructure before it can be mounted as a volume in OpenShift Container Platform. All that is required for Fibre Channel persistent storage is the targetWWNs (array of Fibre Channel target's World Wide Names), a valid LUN number, and filesystem type, and the PersistentVolume API. Note, the number of LUNs must correspond to the number of Persistent Volumes that are created. In the example below, we have LUN as 2, therefore we have created two Persistent Volume definitions.

NOTE

Fiber Channel does not support the 'Recycle' reclaim policy.

Example 21.10. Persistent Volumes Object Definition

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: pv0001
spec:
  capacity:
    storage: 1Gi
  accessModes:
    - ReadWriteOnce
  fc:
    targetWWNs: ['500a0981891b8dc5', '500a0981991b8dc5']
    fsType: ext4
apiVersion: v1
kind: PersistentVolume
metadata:
  name: pv0002
spec:
  capacity:
    storage: 1Gi
  accessModes:
    - ReadOnlyMany
    targetWWNs: ['500a0981891b8dc5', '500a0981991b8dc5']
    lun: 2
    fsType: ext4
```

IMPORTANT

Changing the value of the **fstype** parameter after the volume has been formatted and provisioned can result in data loss and pod failure.

21.9.2.1. Enforcing Disk Quotas

Use LUN partitions to enforce disk quotas and size constraints. Each LUN is one persistent volume. Kubernetes enforces unique names for persistent volumes.

Enforcing quotas in this way allows the end user to request persistent storage by a specific amount (e.g, 10Gi) and be matched with a corresponding volume of equal or greater capacity.

21.9.2.2. Fibre Channel Volume Security

Users request storage with a PersistentVolumeClaim. This claim only lives in the user's namespace and can only be referenced by a pod within that same namespace. Any attempt to access a persistent volume across a namespace causes the pod to fail.

Each Fibre Channel LUN must be accessible by all nodes in the cluster.

21.10. PERSISTENT STORAGE USING AZURE DISK

21.10.1. Overview

OpenShift Container Platform supports Microsoft Azure Disk volumes. You can provision your OpenShift Container Platform cluster with persistent storage using Azure. Some familiarity with Kubernetes and Azure is assumed.

The Kubernetes persistent volume framework allows administrators to provision a cluster with persistent storage and gives users a way to request those resources without having any knowledge of the underlying infrastructure.

Azure Disk volumes can be provisioned dynamically. Persistent volumes are not bound to a single project or namespace; they can be shared across the OpenShift Container Platform cluster. Persistent volume claims, however, are specific to a project or namespace and can be requested by users.

IMPORTANT

High availability of storage in the infrastructure is left to the underlying storage provider.

21.10.2. Prerequisites

Before creating persistent volumes using Azure, ensure your OpenShift Container Platform cluster meets the following requirements:

- OpenShift Container Platform must first be configured for Azure Disk.
- Each node host in the infrastructure must match the Azure virtual machine name.
- Each node host must be in the same resource group.

21.10.3. Provisioning

Storage must exist in the underlying infrastructure before it can be mounted as a volume in OpenShift Container Platform. After ensuring OpenShift Container Platform is configured for Azure Disk, all that is required for OpenShift Container Platform and Azure is an Azure Disk Name and Disk URI and the PersistentVolume API.

21.10.3.1. Creating the Persistent Volume

NOTE

Azure does not support the Recycle reclaim policy.

You must define your persistent volume in an object definition before creating it in OpenShift Container Platform:

Example 21.11. Persistent Volume Object Definition Using Azure

- The name of the volume. This will be how it is identified via persistent volume claims or from pods.
- The amount of storage allocated to this volume.
- This defines the volume type being used (azureDisk plug-in, in this example).
- The name of the data disk in the blob storage.
- The URI the the data disk in the blob storage.
- Host caching mode: None, Read Only, or Read Write.
- File system type to mount (for example, ext4, xfs, and so on).
- B Defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

IMPORTANT

Changing the value of the fsType parameter after the volume is formatted and provisioned can result in data loss and pod failure.

1. Save your definition to a file, for example azure-pv.yaml, and create the persistent volume:

oc create -f azure-pv.yaml
persistentvolume "pv0001" created

2. Verify that the persistent volume was created:

```
# oc get pv
NAME LABELS CAPACITY ACCESSMODES STATUS CLAIM
REASON AGE
pv0001 <none> 5Gi RWO Available
2s
```

Now you can request storage using persistent volume claims, which can now use your new persistent volume.

IMPORTANT

Persistent volume claims only exist in the user's namespace and can only be referenced by a pod within that same namespace. Any attempt to access a persistent volume from a different namespace causes the pod to fail.

21.10.3.2. Volume Format

Before OpenShift Container Platform mounts the volume and passes it to a container, it checks that it contains a file system as specified by the **fsType** parameter in the persistent volume definition. If the device is not formatted with the file system, all data from the device is erased and the device is automatically formatted with the given file system.

This allows unformatted Azure volumes to be used as persistent volumes because OpenShift Container Platform formats them before the first use.

21.11. PERSISTENT STORAGE USING AZURE FILE

21.11.1. Overview

OpenShift Container Platform supports Azure File volumes. You can provision your OpenShift Container Platform cluster with persistent storage using Azure. Some familiarity with Kubernetes and Azure is assumed.

IMPORTANT

High availability of storage in the infrastructure is left to the underlying storage provider.

21.11.2. Before you begin

1. Install samba-client, samba-common, and cifs-utils on all nodes:

\$ sudo yum install samba-client samba-common cifs-utils

2. Enable SELinux booleans on all nodes:

```
$ /usr/sbin/setsebool -P virt_use_samba on
$ /usr/sbin/setsebool -P virt_sandbox_use_samba on
```

21.11.3. Creating the Persistent Volume

NOTE

Azure File does not support the **Recycle** reclaim policy.

21.11.4. Creating the Azure Storage Account Secret

Define the Azure Storage Account name and key in a secret configuration, which is then converted to base64 for use by OpenShift Container Platform.

1. Obtain an Azure Storage Account name and key and encode to base64:

```
apiVersion: v1
kind: Secret
metadata:
  name: azure-secret
type: Opaque
data:
  azurestorageaccountname: azhzdGVzdA==
  azurestorageaccountkey:
eElGMXpKYm5ub2pGTE1Ta0JwNTBteDAyckhzTUsyc2pVN21GdDRMMTNob0I3ZHJBYUo4
akQ2K0E0NDNqSm9nVjd5MkZVT2hRQ1dQbU02WWFOSHk3cWc9PQ==
```

2. Save the secret definition to a file, for example azure-secret.yaml, then create the secret:

```
$ oc create -f azure-secret.yaml
```

3. Verify that the secret was created:

```
$ oc get secret azure-secret
NAME TYPE DATA AGE
azure-secret Opaque 1 23d
```

You must define your persistent volume in an object definition before creating it in OpenShift Container Platform:

Persistent Volume Object Definition Using Azure File

```
apiVersion: "v1"
kind: "PersistentVolume"
metadata:
   name: "pv0001" 1
spec:
   capacity:
   storage: "5120Gi" 2
accessModes:
   - "ReadWriteMany"
azureFile: 3
```

secretName: azure-secret 4

shareName: example 5 readOnly: false 6

- The name of the volume. This is how it is identified via persistent volume claims or from pods.
- The amount of storage allocated to this volume.
- This defines the volume type being used: azureFile plug-in.
- The name of the secret used.
- The name of the file share.
- Defaults to false (read/write). ReadOnly here forces the ReadOnly setting in VolumeMounts.
 - 1. Save your definition to a file, for example *azure-file-pv.yaml*, and create the persistent volume:

```
$ oc create -f azure-file-pv.yaml
persistentvolume "pv0001" created
```

2. Verify that the persistent volume was created:

```
$ oc get pv

NAME LABELS CAPACITY ACCESSMODES STATUS CLAIM

REASON AGE

pv0001 <none> 5Gi RWM Available

2s
```

Now you can request storage using persistent volume claims, which can now use your new persistent volume.

IMPORTANT

Persistent volume claims only exist in the user's namespace and can only be referenced by a pod within that same namespace. Any attempt to access a persistent volume from a different namespace causes the pod to fail.

21.12. DYNAMIC PROVISIONING AND CREATING STORAGE CLASSES

21.12.1. Overview

The StorageClass resource object describes and classifies storage that can be requested, as well as provides a means for passing parameters for dynamically provisioned storage on demand.

StorageClass objects can also serve as a management mechanism for controlling different levels of storage and access to the storage. Cluster Administrators (cluster-admin) or Storage

Administrators (storage-admin) define and create the StorageClass objects that users can request without needing any intimate knowledge about the underlying storage volume sources.

The OpenShift Container Platform persistent volume framework enables this functionality and allows administrators to provision a cluster with persistent storage. The framework also gives users a way to request those resources without having any knowledge of the underlying infrastructure.

Many storage types are available for use as persistent volumes in OpenShift Container Platform. While all of them can be statically provisioned by an administrator, some types of storage are created dynamically using the built-in provider and plug-in APIs.

21.12.2. Available Dynamically Provisioned Plug-ins

OpenShift Container Platform provides the following *provisioner plug-ins*, which have generic implementations for dynamic provisioning that use the cluster's configured provider's API to create new storage resources:

Storage Type	Provisioner Plug-in Name	Required Configuration	Notes
OpenStack Cinder	kubernetes.io/ci nder	Configuring for OpenStack	
AWS Elastic Block Store (EBS)	kubernetes.io/aw s-ebs	Configuring for AWS	For dynamic provisioning when using multiple clusters in different zones, tag each node with Key=KubernetesCl uster, Value=clus terid.
GCE Persistent Disk (gcePD)	kubernetes.io/gc e-pd	Configuring for GCE	In multi-zone configurations, it is advisable to run one Openshift cluster per GCE project to avoid PVs from getting created in zones where no node from current cluster exists.
GlusterFS	kubernetes.io/gl usterfs	Container Native Storage with GlusterFS	Container Native Storage (CNS) utilizes Heketi to manage Gluster Storage.
Ceph RBD	kubernetes.io/rb d	Configuring for OpenStack	
Trident from NetApp	netapp.io/triden t	Configuring for Trident	Storage orchestrator for NetApp ONTAP, SolidFire, and E-Series storage.

IMPORTANT

Any chosen provisioner plug-in also requires configuration for the relevant cloud, host, or third-party provider as per the relevant documentation.

21.12.3. Defining a StorageClass

StorageClass objects are currently a globally scoped object and need to be created by **cluster-admin** or **storage-admin** users. There are currently five plug-ins that are supported. The following sections describe the basic object definition for a *StorageClass* and specific examples for each of the supported plug-in types.

21.12.3.1. Basic StorageClass Object Definition

StorageClass Basic Object Definition

- (required) The API object type.
- (required) The current apiVersion.
- (required) The name of the StorageClass.
- (optional) Annotations for the StorageClass
- 5 (required) The type of provisioner associated with this storage class.
- (optional) The parameters required for the specific provisioner, this will change from plug-in to plug-in.

21.12.3.2. StorageClass Annotations

To set a StorageClass as the cluster-wide default:

```
storageclass.beta.kubernetes.io/is-default-class: "true"
```

This enables any Persistent Volume Claim (PVC) that does not specify a specific volume to automatically be provisioned through the *default* StorageClass

To set a StorageClass description:

```
kubernetes.io/description: My StorageClass Description
```

21.12.3.3. OpenStack Cinder Object Defintion

cinder-storageclass.yaml

kind: StorageClass
apiVersion: storage.k8s.io/v1beta1
metadata:
 name: gold
provisioner: kubernetes.io/cinder
parameters:
 type: fast 1
 availability: nova 2

- VolumeType created in Cinder. Default is empty.
- Availability Zone. Default is empty.

21.12.3.4. AWS ElasticBlockStore (EBS) Object Defintion

aws-ebs-storageclass.yaml

kind: StorageClass
apiVersion: storage.k8s.io/v1beta1
metadata:
 name: slow
provisioner: kubernetes.io/aws-ebs
parameters:
 type: io1 1
 zone: us-east-1d 2
 zones: us-east-1d, us-east-1c 3
 iopsPerGB: "10" 4
 encrypted: "true" 5
 kmsKeyId: keyvalue 6

- Select from io1, gp2, sc1, st1. The default is gp2. See AWS documentation for valid Amazon Resource Name (ARN) values.
- AWS zone. If no zone is specified, volumes are generally round-robined across all active zones where the OpenShift Container Platform cluster has a node. Zone and zones parameters must not be used at the same time.
- A comma-separated list of AWS zone(s). If no zone is specified, volumes are generally roundrobined across all active zones where the OpenShift Container Platform cluster has a node. Zone and zones parameters must not be used at the same time.
- Only for io1 volumes. I/O operations per second per GiB. The AWS volume plug-in multiplies this with the size of the requested volume to compute IOPS of the volume. The value cap is 20,000 IOPS, which is the maximum supported by AWS. See AWS documentation for further details.
- Denotes whether to encrypt the EBS volume. Valid values are true or false.
- Optional. The full ARN of the key to use when encrypting the volume. If none is supplied, but encypted is set to true, then AWS generates a key. See AWS documentation for a valid ARN value.

21.12.3.5. GCE PersistentDisk (gcePD) Object Defintion

gce-pd-storageclass.yaml

kind: StorageClass
apiVersion: storage.k8s.io/v1beta1
metadata:
 name: slow
provisioner: kubernetes.io/gce-pd
parameters:
 type: pd-standard
 zone: us-central1-a
2

- Select either pd-standard or pd-ssd. The default is pd-ssd.
- GCE zone. If not specified, the zone is randomly chosen from zones in the same region as controller-manager.

21.12.3.6. GlusterFS Object Defintion

glusterfs-storageclass.yaml

```
kind: StorageClass
apiVersion: storage.k8s.io/v1beta1
metadata:
   name: slow
provisioner: kubernetes.io/glusterfs
parameters:
   resturl: "http://127.0.0.1:8081" 1
   restuser: "admin" 2
   secretName: "heketi-secret" 3
   secretNamespace: "default" 4
   gidMin: "40000" 5
   gidMax: "50000" 6
```

- Gluster REST service/Heketi service URL that provisions Gluster volumes on demand. The general format should be {http/https}://{IPaddress}: {Port}. This is a mandatory parameter for the GlusterFS dynamic provisioner. If the Heketi service is exposed as a routable service in the OpenShift Container Platform, it will have a resolvable fully qualified domain name and Heketi service URL. For additional information and configuration, See Container-Native Storage for OpenShift Container Platform.
- Gluster REST service/Heketi user who has access to create volumes in the Gluster Trusted Pool.
- Identification of a Secret instance that contains a user password to use when talking to the Gluster REST service. Optional; an empty password will be used when both secretNamespace and secretName are omitted. The provided secret must be of type "kubernetes.io/glusterfs".
- The namespace of mentioned secretName. Optional; an empty password will be used when both secretNamespace and secretName are omitted. The provided secret must be of type "kubernetes.io/glusterfs".

- Optional. The minimum value of GID range for the storage class.
- Optional. The maximum value of GID range for the storage class.

When the gidMin and gidMax values are not specified, the volume is provisioned with a value between 2000 and 2147483647, which are defaults for gidMin and gidMax respectively. If specified, a unique value (GID) in this range (gidMin-gidMax) is used for dynamically provisioned volumes. The GID of the provisioned volume will be set to this value. It is required to run Heketi version 3 or later to make use of this feature. This GID is released from the pool when the subjected volume is deleted. The GID pool is per storage class, if 2 or more storage classes have GID ranges that overlap there will be duplicate GIDs dispatched by the provisioner.

When the persistent volumes are dynamically provisioned, the Gluster plug-in automatically creates an endpoint and a headless service of the name gluster-dynamic-<claimname>. When the persistent volume claim is deleted, this dynamic endpoint and service is deleted automatically.

Example of a Secret

```
apiVersion: v1
kind: Secret
metadata:
  name: heketi-secret
  namespace: default
data:
  # base64 encoded password. E.g.: echo -n "mypassword" | base64
  key: bXlwYXNzd29yZA==
type: kubernetes.io/glusterfs
```

21.12.3.7. Ceph RBD Object Definition

ceph-storageclass.yaml

- 1 Ceph monitors, comma-delimited. It is required.
- Ceph client ID that is capable of creating images in the pool. Default is "admin".
- 3 Secret Name for adminId. It is required. The provided secret must have type "kubernetes.io/rbd".
- The namespace for adminSecret. Default is "default".

- Ceph RBD pool. Default is "rbd".
- Ceph client ID that is used to map the Ceph RBD image. Default is the same as adminId.
- The name of Ceph Secret for userId to map Ceph RBD image. It must exist in the same namespace as PVCs. It is required.

21.12.3.8. Trident Object Definition

trident.yaml

```
apiVersion: storage.k8s.io/v1beta1
kind: StorageClass
metadata:
   name: gold
provisioner: netapp.io/trident 1
parameters: 2
   media: "ssd"
   provisioningType: "thin"
   snapshots: "true"
```

Trident uses the parameters as selection criteria for the different pools of storage that are registered with it. Trident itself is configured separately.

- For more information about installing Trident with OpenShift Container Platform, see the Trident documentation.
- For more information about supported parameters, see the storage attributes section of the Trident documentation.

21.12.4. Additional Information and Examples

- Examples and uses of StorageClasses for Dynamic Provisioning
- Examples and uses of StorageClasses without Dynamic Provisioning

21.13. VOLUME SECURITY

21.13.1. Overview

This topic provides a general guide on pod security as it relates to volume security. For information on pod-level security in general, see Managing Security Context Constraints (SCC) and the Security Context Constraint concept topic. For information on the OpenShift Container Platform persistent volume (PV) framework in general, see the Persistent Storage concept topic.

Accessing persistent storage requires coordination between the cluster and/or storage administrator and the end developer. The cluster administrator creates PVs, which abstract the underlying physical storage. The developer creates pods and, optionally, PVCs, which bind to PVs, based on matching criteria, such as capacity.

Multiple persistent volume claims (PVCs) within the same project can bind to the same PV. However, once a PVC binds to a PV, that PV cannot be bound by a claim outside of the first claim's project. If the

underlying storage needs to be accessed by multiple projects, then each project needs its own PV, which can point to the same physical storage. In this sense, a bound PV is tied to a project. For a detailed PV and PVC example, see the guide for WordPress and MySQL using NFS.

For the cluster administrator, granting pods access to PVs involves:

- knowing the group ID and/or user ID assigned to the actual storage,
- understanding SELinux considerations, and
- ensuring that these IDs are allowed in the range of legal IDs defined for the project and/or the SCC that matches the requirements of the pod.

Group IDs, the user ID, and SELinux values are defined in the **SecurityContext** section in a pod definition. Group IDs are global to the pod and apply to all containers defined in the pod. User IDs can also be global, or specific to each container. Four sections control access to volumes:

- supplementalGroups
- fsGroup
- runAsUser
- seLinuxOptions

21.13.2. SCCs, Defaults, and Allowed Ranges

SCCs influence whether or not a pod is given a default user ID, fsGroup ID, supplemental group ID, and SELinux label. They also influence whether or not IDs supplied in the pod definition (or in the image) will be validated against a range of allowable IDs. If validation is required and fails, then the pod will also fail.

SCCs define strategies, such as runAsUser, supplementalGroups, and fsGroup. These strategies help decide whether the pod is authorized. Strategy values set to RunAsAny are essentially stating that the pod can do what it wants regarding that strategy. Authorization is skipped for that strategy and no OpenShift Container Platform default is produced based on that strategy. Therefore, IDs and SELinux labels in the resulting container are based on container defaults instead of OpenShift Container Platform policies.

For a quick summary of **RunAsAny**:

- Any ID defined in the pod definition (or image) is allowed.
- Absence of an ID in the pod definition (and in the image) results in the container assigning an ID, which is **root** (0) for Docker.
- No SELinux labels are defined, so Docker will assign a unique label.

For these reasons, SCCs with RunAsAny for ID-related strategies should be protected so that ordinary developers do not have access to the SCC. On the other hand, SCC strategies set to MustRunAs or MustRunAsRange trigger ID validation (for ID-related strategies), and cause default values to be supplied by OpenShift Container Platform to the container when those values are not supplied directly in the pod definition or image.

CAUTION

Allowing access to SCCs with a RunAsAny FSGroup strategy can also prevent users from accessing their block devices. Pods need to specify an fsGroup in order to take over their block devices. Normally, this is done when the SCC FSGroup strategy is set to MustRunAs. If a user's pod is assigned an SCC with a RunAsAny FSGroup strategy, then the user may face permission denied errors until they discover that they need to specify an fsGroup themselves.

SCCs may define the range of allowed IDs (user or groups). If range checking is required (for example, using MustRunAs) and the allowable range is not defined in the SCC, then the project determines the ID range. Therefore, projects support ranges of allowable ID. However, unlike SCCs, projects do not define strategies, such as runAsUser.

Allowable ranges are helpful not only because they define the boundaries for container IDs, but also because the minimum value in the range becomes the default value for the ID in question. For example, if the SCC ID strategy value is **MustRunAs**, the minimum value of an ID range is **100**, and the ID is absent from the pod definition, then 100 is provided as the default for this ID.

As part of pod admission, the SCCs available to a pod are examined (roughly, in priority order followed by most restrictive) to best match the requests of the pod. Setting a SCC's strategy type to RunAsAny is less restrictive, whereas a type of MustRunAs is more restrictive. All of these strategies are evaluated. To see which SCC was assigned to a pod, use the oc get pod command:

```
# oc get pod <pod_name> -o yaml
...
metadata:
   annotations:
    openshift.io/scc: nfs-scc 1
   name: nfs-pod1 2
   namespace: default 3
...
```

- Name of the SCC that the pod used (in this case, a custom SCC).
- 2 Name of the pod.
- Name of the project. "Namespace" is interchangeable with "project" in OpenShift Container Platform. See Projects and Users for details.

It may not be immediately obvious which SCC was matched by a pod, so the command above can be very useful in understanding the UID, supplemental groups, and SELinux relabeling in a live container.

Any SCC with a strategy set to **RunAsAny** allows specific values for that strategy to be defined in the pod definition (and/or image). When this applies to the user ID (**runAsUser**) it is prudent to restrict access to the SCC to prevent a container from being able to run as root.

Because pods often match the **restricted** SCC, it is worth knowing the security this entails. The **restricted** SCC has the following characteristics:

• User IDs are constrained due to the runAsUser strategy being set to MustRunAsRange. This forces user ID validation.

- Because a range of allowable user IDs is not defined in the SCC (see oc export scc restricted for more details), the project's openshift.io/sa.scc.uid-range range will be used for range checking and for a default ID, if needed.
- A default user ID is produced when a user ID is not specified in the pod definition and the matching SCC's runAsUser is set to MustRunAsRange.
- An SELinux label is required (seLinuxContext set to MustRunAs), which uses the project's default MCS label.
- fsGroup IDs are constrained to a single value due to the FSGroup strategy being set to MustRunAs, which dictates that the value to use is the minimum value of the first range specified.
- Because a range of allowable fsGroup IDs is not defined in the SCC, the minimum value of the project's openshift.io/sa.scc.supplemental-groups range (or the same range used for user IDs) will be used for validation and for a default ID, if needed.
- A default fsGroup ID is produced when a fsGroup ID is not specified in the pod and the matching SCC's FSGroup is set to MustRunAs.
- Arbitrary supplemental group IDs are allowed because no range checking is required. This is a result of the supplementalGroups strategy being set to RunAsAny.
- Default supplemental groups are not produced for the running pod due to **RunAsAny** for the two group strategies above. Therefore, if no groups are defined in the pod definition (or in the image), the container(s) will have no supplemental groups predefined.

The following shows the **default** project and a custom SCC (**my-custom-scc**), which summarizes the interactions of the SCC and the project:

```
$ oc get project default -o yaml 1
metadata:
  annotations: 2
    openshift.io/sa.scc.mcs: s0:c1,c0 3
    openshift.io/sa.scc.supplemental-groups: 1000000000/10000 4
    openshift.io/sa.scc.uid-range: 1000000000/10000 5
$ oc get scc my-custom-scc -o yaml
fsGroup:
  type: MustRunAs 6
  ranges:
  - min: 5000
    max: 6000
runAsUser:
  type: MustRunAsRange 7
  uidRangeMin: 1000100000
  uidRangeMax: 1000100999
seLinuxContext: 8
  type: MustRunAs
  SELinuxOptions: 9
    user: <selinux-user-name>
    role: ...
```

type: ...
level: ...
supplementalGroups:
type: MustRunAs 10

ranges: - min: 5000 max: 6000

- **default** is the name of the project.
- Default values are only produced when the corresponding SCC strategy is not RunAsAny.
- SELinux default when not defined in the pod definition or in the SCC.
- Range of allowable group IDs. ID validation only occurs when the SCC strategy is **RunAsAny**. There can be more than one range specified, separated by commas. See below for supported formats.
- Same as <4> but for user IDs. Also, only a single range of user IDs is supported.
- 6 10 MustRunAs enforces group ID range checking and provides the container's groups default. Based on this SCC definition, the default is 5000 (the minimum ID value). If the range was omitted from the SCC, then the default would be 1000000000 (derived from the project). The other supported type, RunAsAny, does not perform range checking, thus allowing any group ID, and produces no default groups.
- MustRunAsRange enforces user ID range checking and provides a UID default. Based on this SCC, the default UID is 1000100000 (the minimum value). If the minimum and maximum range were omitted from the SCC, the default user ID would be 1000000000 (derived from the project).

 MustRunAsNonRoot and RunAsAny are the other supported types. The range of allowed IDs can be defined to include any user IDs required for the target storage.
- When set to MustRunAs, the container is created with the SCC's SELinux options, or the MCS default defined in the project. A type of RunAsAny indicates that SELinux context is not required, and, if not defined in the pod, is not set in the container.
- The SELinux user name, role name, type, and labels can be defined here.

Two formats are supported for allowed ranges:

- 1. M/N, where M is the starting ID and N is the count, so the range becomes M through (and including) M+N-1.
- 2. M-N, where M is again the starting ID and N is the ending ID. The default group ID is the starting ID in the first range, which is 1000000000 in this project. If the SCC did not define a minimum group ID, then the project's default ID is applied.

21.13.3. Supplemental Groups

NOTE

Read SCCs, Defaults, and Allowed Ranges before working with supplemental groups.

TIP

It is generally preferable to use group IDs (supplemental or fsGroup) to gain access to persistent storage versus using user IDs.

Supplemental groups are regular Linux groups. When a process runs in Linux, it has a UID, a GID, and one or more supplemental groups. These attributes can be set for a container's main process. The supplementalGroups IDs are typically used for controlling access to shared storage, such as NFS and GlusterFS, whereas fsGroup is used for controlling access to block storage, such as Ceph RBD and iSCSI.

The OpenShift Container Platform shared storage plug-ins mount volumes such that the POSIX permissions on the mount match the permissions on the target storage. For example, if the target storage's owner ID is **1234** and its group ID is **5678**, then the mount on the host node and in the container will have those same IDs. Therefore, the container's main process must match one or both of those IDs in order to access the volume.

For example, consider the following NFS export.

On an OpenShift Container Platform node:

NOTE

showmount requires access to the ports used by rpcbind and rpc.mount on the NFS
server

```
# showmount -e <nfs-server-ip-or-hostname>
Export list for f21-nfs.vm:
/opt/nfs *
```

On the NFS server:

```
# cat /etc/exports
/opt/nfs *(rw,sync,root_squash)
...

# ls -lZ /opt/nfs -d
drwx-----. 1000100001 5555 unconfined_u:object_r:usr_t:s0 /opt/nfs
```

The /opt/nfs/ export is accessible by UID 1000100001 and the group 5555. In general, containers should not run as root. So, in this NFS example, containers which are not run as UID 1000100001 and are not members the group 5555 will not have access to the NFS export.

Often, the SCC matching the pod does not allow a specific user ID to be specified, thus using supplemental groups is a more flexible way to grant storage access to a pod. For example, to grant NFS access to the export above, the group **5555** can be defined in the pod definition:

```
apiVersion: v1
kind: Pod
...
spec:
containers:
- name: ...
volumeMounts:
```

```
- name: nfs 1
   mountPath: /usr/share/... 2
securityContext: 3
   supplementalGroups: [5555] 4
volumes:
- name: nfs 5
   nfs:
      server: <nfs_server_ip_or_host>
      path: /opt/nfs 6
```

- Name of the volume mount. Must match the name in the volumes section.
- NFS export path as seen in the container.
- Pod global security context. Applies to all containers inside the pod. Each container can also define its securityContext, however group IDs are global to the pod and cannot be defined for individual containers.
- Supplemental groups, which is an array of IDs, is set to 5555. This grants group access to the export.
- Name of the volume. Must match the name in the volumeMounts section.
- Actual NFS export path on the NFS server.

All containers in the above pod (assuming the matching SCC or project allows the group **5555**) will be members of the group **5555** and have access to the volume, regardless of the container's user ID. However, the assumption above is critical. Sometimes, the SCC does not define a range of allowable group IDs but instead requires group ID validation (a result of **supplementalGroups** set to **MustRunAs**). Note that this is **not** the case for the **restricted** SCC. The project will not likely allow a group ID of **5555**, unless the project has been customized to access this NFS export. So, in this scenario, the above pod will fail because its group ID of **5555** is not within the SCC's or the project's range of allowed group IDs.

Supplemental Groups and Custom SCCs

To remedy the situation in the previous example, a custom SCC can be created such that:

- a minimum and max group ID are defined,
- ID range checking is enforced, and
- the group ID of **5555** is allowed.

It is often better to create a new SCC rather than modifying a predefined SCC, or changing the range of allowed IDs in the predefined projects.

The easiest way to create a new SCC is to export an existing SCC and customize the YAML file to meet the requirements of the new SCC. For example:

1. Use the restricted SCC as a template for the new SCC:

```
$ oc export scc restricted > new-scc.yaml
```

2. Edit the *new-scc.yaml* file to your desired specifications.

3. Create the new SCC:

\$ oc create -f new-scc.yaml

NOTE

The oc edit scc command can be used to modify an instantiated SCC.

Here is a fragment of a new SCC named **nfs-scc**:

```
$ oc export scc nfs-scc

allowHostDirVolumePlugin: false 1
...
kind: SecurityContextConstraints
metadata:
...
name: nfs-scc 2
priority: 9 3
...
supplementalGroups:
type: MustRunAs 4
ranges:
- min: 5000 5
max: 6000
...
```

- The allow booleans are the same as for the restricted SCC.
- Name of the new SCC.
- Numerically larger numbers have greater priority. Nil or omitted is the lowest priority. Higher priority SCCs sort before lower priority SCCs and thus have a better chance of matching a new pod.
- supplementalGroups is a strategy and it is set to MustRunAs, which means group ID checking is required.
- Multiple ranges are supported. The allowed group ID range here is 5000 through 5999, with the default supplemental group being 5000.

When the same pod shown earlier runs against this new SCC (assuming, of course, the pod matches the new SCC), it will start because the group **5555**, supplied in the pod definition, is now allowed by the custom SCC.

21.13.4. fsGroup

NOTE

Read SCCs, Defaults, and Allowed Ranges before working with supplemental groups.

TIP

It is generally preferable to use group IDs (supplemental or fsGroup) to gain access to persistent storage versus using user IDs.

fsGroup defines a pod's "file system group" ID, which is added to the container's supplemental groups. The **supplementalGroups** ID applies to shared storage, whereas the **fsGroup** ID is used for block storage.

Block storage, such as Ceph RBD, iSCSI, and various cloud storage, is typically dedicated to a single pod which has requested the block storage volume, either directly or using a PVC. Unlike shared storage, block storage is taken over by a pod, meaning that user and group IDs supplied in the pod definition (or image) are applied to the actual, physical block device. Typically, block storage is not shared.

A fsGroup definition is shown below in the following pod definition fragment:

```
kind: Pod
...
spec:
containers:
- name: ...
securityContext: 1
fsGroup: 5555 2
```

- As with supplementalGroups, fsGroup must be defined globally to the pod, not per container.
- 5555 will become the group ID for the volume's group permissions and for all new files created in the volume.

As with supplementalGroups, all containers in the above pod (assuming the matching SCC or project allows the group 5555) will be members of the group 5555, and will have access to the block volume, regardless of the container's user ID. If the pod matches the restricted SCC, whose fsGroup strategy is MustRunAs, then the pod will fail to run. However, if the SCC has its fsGroup strategy set to RunAsAny, then any fsGroup ID (including 5555) will be accepted. Note that if the SCC has its fsGroup strategy set to RunAsAny and no fsGroup ID is specified, the "taking over" of the block storage does not occur and permissions may be denied to the pod.

fsGroups and Custom SCCs

To remedy the situation in the previous example, a custom SCC can be created such that:

- a minimum and maximum group ID are defined,
- ID range checking is enforced, and
- the group ID of **5555** is allowed.

It is better to create new SCCs versus modifying a predefined SCC, or changing the range of allowed IDs in the predefined projects.

Consider the following fragment of a new SCC definition:

```
# oc export scc new-scc
...
kind: SecurityContextConstraints
...
fsGroup:
   type: MustRunAs 1
   ranges: 2
   - max: 6000
    min: 5000 3
...
```

- MustRunAs triggers group ID range checking, whereas RunAsAny does not require range checking.
- The range of allowed group IDs is 5000 through, and including, 5999. Multiple ranges are supported but not used. The allowed group ID range here is 5000 through 5999, with the default fsGroup being 5000.
- The minimum value (or the entire range) can be omitted from the SCC, and thus range checking and generating a default value will defer to the project's openshift.io/sa.scc.supplemental-groups range. fsGroup and supplementalGroups use the same group field in the project; there is not a separate range for fsGroup.

When the pod shown above runs against this new SCC (assuming, of course, the pod matches the new SCC), it will start because the group **5555**, supplied in the pod definition, is allowed by the custom SCC. Additionally, the pod will "take over" the block device, so when the block storage is viewed by a process outside of the pod, it will actually have **5555** as its group ID.

A list of volumes supporting block ownership include:

- AWS Elastic Block Store
- OpenStack Cinder
- Ceph RBD
- GCE Persistent Disk
- iSCSI
- emptyDir
- gitRepo

NOTE

This list is potentially incomplete.

21.13.5. User IDs

NOTE

Read SCCs, Defaults, and Allowed Ranges before working with supplemental groups.

TIP

It is generally preferable to use group IDs (supplemental or fsGroup) to gain access to persistent storage versus using user IDs.

User IDs can be defined in the container image or in the pod definition. In the pod definition, a single user ID can be defined globally to all containers, or specific to individual containers (or both). A user ID is supplied as shown in the pod definition fragment below:

spec:
 containers:
 name: ...
 securityContext:
 runAsUser: 1000100001

ID 1000100001 in the above is container-specific and matches the owner ID on the export. If the NFS export's owner ID was **54321**, then that number would be used in the pod definition. Specifying **securityContext** outside of the container definition makes the ID global to all containers in the pod.

Similar to group IDs, user IDs may be validated according to policies set in the SCC and/or project. If the SCC's runAsUser strategy is set to RunAsAny, then any user ID defined in the pod definition or in the image is allowed.

WARNING

This means even a UID of 0 (root) is allowed.

If, instead, the runAsUser strategy is set to MustRunAsRange, then a supplied user ID will be validated against a range of allowed IDs. If the pod supplies no user ID, then the default ID is set to the minimum value of the range of allowable user IDs.

Returning to the earlier NFS example, the container needs its UID set to 1000100001, which is shown in the pod fragment above. Assuming the **default** project and the **restricted** SCC, the pod's requested user ID of 1000100001 will not be allowed, and therefore the pod will fail. The pod fails because:

- it requests 1000100001 as its user ID,
- all available SCCs use MustRunAsRange for their runAsUser strategy, so UID range checking is required, and
- 1000100001 is not included in the SCC or in the project's user ID range.

To remedy this situation, a new SCC can be created with the appropriate user ID range. A new project could also be created with the appropriate user ID range defined. There are also other, less-preferred options:

 The restricted SCC could be modified to include 1000100001 within its minimum and maximum user ID range. This is not recommended as you should avoid modifying the predefined SCCs if possible.

- The **restricted** SCC could be modified to use **RunAsAny** for the **runAsUser** value, thus eliminating ID range checking. This is *strongly* not recommended, as containers could run as root.
- The default project's UID range could be changed to allow a user ID of 1000100001. This is not
 generally advisable because only a single range of user IDs can be specified, and thus other
 pods may not run if the range is altered.

User IDs and Custom SCCs

It is good practice to avoid modifying the predefined SCCs if possible. The preferred approach is to create a custom SCC that better fits an organization's security needs, or create a new project that supports the desired user IDs.

To remedy the situation in the previous example, a custom SCC can be created such that:

- a minimum and maximum user ID is defined,
- UID range checking is still enforced, and
- the UID of 1000100001 is allowed.

For example:

```
$ oc export scc nfs-scc

allowHostDirVolumePlugin: false 1
...
kind: SecurityContextConstraints
metadata:
...
name: nfs-scc 2
priority: 9 3
requiredDropCapabilities: null
runAsUser:
  type: MustRunAsRange 4
  uidRangeMax: 1000100001 5
  uidRangeMin: 1000100001
...
```

- The allowXX bools are the same as for the restricted SCC.
- The name of this new SCC is **nfs-scc**.
- Numerically larger numbers have greater priority. Nil or omitted is the lowest priority. Higher priority SCCs sort before lower priority SCCs, and thus have a better chance of matching a new pod.
- The runAsUser strategy is set to MustRunAsRange, which means UID range checking is enforced.
- The UID range is 1000100001 through 1000100001 (a range of one value).

Now, with runAsUser: 1000100001 shown in the previous pod definition fragment, the pod matches the new nfs-scc and is able to run with a UID of 1000100001.

21.13.6. SELinux Options

All predefined SCCs, except for the **privileged** SCC, set the **seLinuxContext** to **MustRunAs**. So the SCCs most likely to match a pod's requirements will force the pod to use an SELinux policy. The SELinux policy used by the pod can be defined in the pod itself, in the image, in the SCC, or in the project (which provides the default).

SELinux labels can be defined in a pod's securityContext.seLinuxOptions section, and supports user, role, type, and level:

NOTE

Level and MCS label are used interchangeably in this topic.

```
securityContext: 1
seLinuxOptions:
    level: "s0:c123,c456" 2
...
```

- 1evel can be defined globally for the entire pod, or individually for each container.
- SELinux level label.

Here are fragments from an SCC and from the **default** project:

```
$ oc export scc scc-name
...
seLinuxContext:
   type: MustRunAs 1

# oc export project default
...
metadata:
   annotations:
    openshift.io/sa.scc.mcs: s0:c1,c0 2
...
```

- MustRunAs causes volume relabeling.
- 2 If the label is not provided in the pod or in the SCC, then the default comes from the project.

All predefined SCCs, except for the **privileged** SCC, set the **seLinuxContext** to **MustRunAs**. This forces pods to use MCS labels, which can be defined in the pod definition, the image, or provided as a default.

The SCC determines whether or not to require an SELinux label and can provide a default label. If the seLinuxContext strategy is set to MustRunAs and the pod (or image) does not define a label, OpenShift Container Platform defaults to a label chosen from the SCC itself or from the project.

If seLinuxContext is set to RunAsAny, then no default labels are provided, and the container determines the final label. In the case of Docker, the container will use a unique MCS label, which will

not likely match the labeling on existing storage mounts. Volumes which support SELinux management will be relabeled so that they are accessible by the specified label and, depending on how exclusionary the label is, only that label.

This means two things for unprivileged containers:

- The volume will be given a type which is accessible by unprivileged containers. This type is usually svirt_sandbox_file_t.
- If a level is specified, the volume will be labeled with the given MCS label.

For a volume to be accessible by a pod, the pod must have both categories of the volume. So a pod with s0:c1,c2 will be able to access a volume with s0:c1,c2. A volume with s0 will be accessible by all pods.

If pods fail authorization, or if the storage mount is failing due to permissions errors, then there is a possibility that SELinux enforcement is interfering. One way to check for this is to run:

ausearch -m avc --start recent

This examines the log file for AVC (Access Vector Cache) errors.

21.14. SELECTOR-LABEL VOLUME BINDING

21.14.1. Overview

This guide provides the steps necessary to enable binding of persistent volume claims (PVCs) to persistent volumes (PVs) via **selector** and **label** attributes. By implementing selectors and labels, regular users are able to target provisioned storage by identifiers defined by a cluster administrator.

21.14.2. Motivation

In cases of statically provisioned storage, developers seeking persistent storage are required to know a handful identifying attributes of a PV in order to deploy and bind a PVC. This creates several problematic situations. Regular users might have to contact a cluster administrator to either deploy the PVC or provide the PV values. PV attributes alone do not convey the intended use of the storage volumes, nor do they provide methods by which volumes can be grouped.

Selector and label attributes can be used to abstract away PV details from the user while providing cluster administrators a way of identifying volumes by a descriptive and customizable tag. Through the selector-label method of binding, users are only required to know which labels are defined by the administrator.

NOTE

The selector-label feature is currently only available for *statically* provisioned storage and is currently not implemented for storage provisioned dynamically.

21.14.3. Deployment

This section reviews how to define and deploy PVCs.

21.14.3.1. Prerequisites

1. A running OpenShift Container Platform 3.3+ cluster

- 2. A volume provided by a supported storage provider
- 3. A user with a cluster-admin role binding

21.14.3.2. Define the Persistent Volume and Claim

1. As the **cluser-admin** user, define the PV. For this example, we will be using a **GlusterFS** volume. See the appropriate storage provider for your provider's configuration.

Example 21.12. Persistent Volume with Labels

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: gluster-volume
  labels: 1
    volume-type: ssd
    aws-availability-zone: us-east-1
spec:
  capacity:
    storage: 2Gi
  accessModes:
    - ReadWriteMany
  glusterfs:
    endpoints: glusterfs-cluster
    path: myVol1
    readOnly: false
  persistentVolumeReclaimPolicy: Recycle
```

- A PVC whose selectors match *all* of a PV's labels will be bound, assuming a PV is available.
- 2. Define the PVC:

Example 21.13. Persistent Volume Claim with Selectors

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
   name: gluster-claim
spec:
   accessModes:
   - ReadWriteMany
   resources:
       requests:
       storage: 1Gi
   selector: 1
      matchLabels: 2
       volume-type: ssd
       aws-availability-zone: us-east-1
```

- Begin **selectors** section.
- 2

List all labels by which the user is requesting storage. Must match *all* labels of targeted PV.

21.14.3.3. Deploy the Persistent Volume and Claim

As the **cluster-admin** user, create the persistent volume:

Example 21.14. Create the Persistent Volume

```
# oc create -f gluster-pv.yaml
persistentVolume "gluster-volume" created
# oc get pv
                        LABELS
                                               ACCESSMODES
                                                             STATUS
NAME
                                  CAPACITY
CLAIM
        REASON
                   AGE
gluster-volume
                         map[]
                                  2147483648
Available
                               2s
```

Once the PV is created, any user whose selectors match all its labels can create their PVC.

Example 21.15. Create the Persistent Volume Claim

21.15. ENABLING CONTROLLER-MANAGED ATTACHMENT AND DETACHMENT

21.15.1. Overview

As of OpenShift Container Platform 3.4, administrators can enable the controller running on the cluster's master to manage volume attach and detach operations on behalf of a set of nodes, as opposed to letting them manage their own volume attach and detach operations.

Enabling controller-managed attachment and detachment has the following benefits:

- If a node is lost, volumes that were attached to it can be detached by the controller and reattached elsewhere.
- Credentials for attaching and detaching do not need to be made present on every node, improving security.

As of OpenShift Container Platform 3.6, controller-managed attachment and detachment is the default setting.

21.15.2. Determining What Is Managing Attachment and Detachment

If a node has set the annotation **volumes**. **kubernetes**.io/controller-managed-attach-detach on itself, then its attach and detach operations are being managed by the controller. The controller will automatically inspect all nodes for this annotation and act according to whether it is present or not. Therefore, you may inspect the node for this annotation to determine if it has enabled controller-managed attach and detach.

To further ensure that the node is opting for controller-managed attachment and detachment, its logs can be searched for the following line:

Setting node annotation to enable volume controller attach/detach

If the above line is not found, the logs should instead contain:

Controller attach/detach is disabled for this node; Kubelet will attach and detach volumes

To check from the controller's end that it is managing a particular node's attach and detach operations, the logging level must first be set to at least 4. Then, the following line should be found:

processVolumesInUse for node <node_hostname>

For information on how to view logs and configure logging levels, see Configuring Logging Levels.

21.15.3. Configuring Nodes to Enable Controller-managed Attachment and Detachment

Enabling controller-managed attachment and detachment is done by configuring individual nodes to opt in and disable their own node-level attachment and detachment management. See Node Configuration Files for information on what node configuration file to edit and add the following:

```
kubeletArguments:
   enable-controller-attach-detach:
    "true"
```

Once a node is configured, it must be restarted for the setting to take effect.

CHAPTER 22. PERSISTENT STORAGE EXAMPLES

22.1. OVERVIEW

The following sections provide detailed, comprehensive instructions on setting up and configuring common storage use cases. These examples cover both the administration of persistent volumes and their security, and how to claim against the volumes as a user of the system.

- Sharing an NFS PV Across Two Pods
- Ceph-RBD Block Storage Volume
- Shared Storage Using a GlusterFS Volume
- Dynamic Provisioning Storage Using GlusterFS
- Mounting a PV to Privileged Pods
- Backing Docker Registry with GlusterFS Storage
- Binding Persistent Volumes by Labels
- Using StorageClasses for Dynamic Provisioning
- Using StorageClasses for Existing Legacy Storage
- Configuring Azure Blob Storage for Integrated Docker Registry

22.2. SHARING AN NFS MOUNT ACROSS TWO PERSISTENT VOLUME CLAIMS

22.2.1. Overview

The following use case describes how a cluster administrator wanting to leverage shared storage for use by two separate containers would configure the solution. This example highlights the use of NFS, but can easily be adapted to other shared storage types, such as GlusterFS. In addition, this example will show configuration of pod security as it relates to shared storage.

Persistent Storage Using NFS provides an explanation of persistent volumes (PVs), persistent volume claims (PVCs), and using NFS as persistent storage. This topic shows and end-to-end example of using an existing NFS cluster and OpenShift Container Platform persistent store, and assumes an existing NFS server and exports exist in your OpenShift Container Platform infrastructure.

NOTE

All oc commands are executed on the OpenShift Container Platform master host.

22.2.2. Creating the Persistent Volume

Before creating the PV object in OpenShift Container Platform, the persistent volume (PV) file is defined:

Example 22.1. Persistent Volume Object Definition Using NFS

```
apiVersion: v1
kind: PersistentVolume
metadata:
   name: nfs-pv 1
spec:
   capacity:
    storage: 1Gi 2
   accessModes:
    - ReadWriteMany 3
   persistentVolumeReclaimPolicy: Retain 4
   nfs: 5
     path: /opt/nfs 6
     server: nfs.f22 7
   readOnly: false
```

- The name of the PV, which is referenced in pod definitions or displayed in various oc volume commands.
- The amount of storage allocated to this volume.
- accessModes are used as labels to match a PV and a PVC. They currently do not define any form of access control.
- The volume reclaim policy **Retain** indicates that the volume will be preserved after the pods accessing it terminates.
- This defines the volume type being used, in this case the **NFS** plug-in.
- This is the NFS mount path.
- This is the NFS server. This can also be specified by IP address.

Save the PV definition to a file, for example nfs-pv.yaml, and create the persistent volume:

```
# oc create -f nfs-pv.yaml
persistentvolume "nfs-pv" created
```

Verify that the persistent volume was created:

```
# oc get pv
NAME LABELS CAPACITY ACCESSMODES STATUS CLAIM
REASON AGE
nfs-pv <none> 1Gi RWX Available
37s
```

22.2.3. Creating the Persistent Volume Claim

A persistent volume claim (PVC) specifies the desired access mode and storage capacity. Currently, based on only these two attributes, a PVC is bound to a single PV. Once a PV is bound to a PVC, that PV is essentially tied to the PVC's project and cannot be bound to by another PVC. There is a one-to-one

mapping of PVs and PVCs. However, multiple pods in the same project can use the same PVC. This is the use case we are highlighting in this example.

Example 22.2. PVC Object Definition

apiVersion: v1
kind: PersistentVolumeClaim
metadata:
 name: nfs-pvc 1
spec:
 accessModes:
 - ReadWriteMany
 resources:
 requests:
 storage: 1Gi 3

- The claim name is referenced by the pod under its volumes section.
- As mentioned above for PVs, the accessModes do not enforce access right, but rather act as labels to match a PV to a PVC.
- 3 This claim will look for PVs offering 1Gi or greater capacity.

Save the PVC definition to a file, for example *nfs-pvc.yaml*, and create the PVC:

```
# oc create -f nfs-pvc.yaml
persistentvolumeclaim "nfs-pvc" created
```

Verify that the PVC was created and bound to the expected PV:

# oc get pvc NAME	LABELS	STATUS	VOLUME	CAPACITY	ACCESSMODES
AGE nfs-pvc	<none></none>	Bound	nfs-pv	1Gi	RWX
24s			1		

The claim, **nfs-pvc**, was bound to the **nfs-pv** PV.

22.2.4. Ensuring NFS Volume Access

Access is necessary to a node in the NFS server. On this node, examine the NFS export mount:

- the owner has ID 0.
- the group has ID 100003.

In order to access the NFS mount, the container must match the SELinux label, and either run with a UID of 0, or with 100003 in its supplemental groups range. Gain access to the volume by matching the NFS mount's groups, which will be defined in the pod definition below.

By default, SELinux does not allow writing from a pod to a remote NFS server. To enable writing to NFS volumes with SELinux enforcing on each node, run:

```
# setsebool -P virt_use_nfs on
```

22.2.5. Creating the Pod

A pod definition file or a template file can be used to define a pod. Below is a pod specification that creates a single container and mounts the NFS volume for read-write access:

Example 22.3. Pod Object Definition

```
apiVersion: v1
kind: Pod
metadata:
  name: nginx-nfs-pod 1
  labels:
    name: nginx-nfs-pod
spec:
  containers:
    - name: nginx-nfs-pod
      image: fedora/nginx 2
      ports:
        - name: web
          containerPort: 80
      volumeMounts:
        - name: nfsvol 3
          mountPath: /usr/share/nginx/html 4
  securityContext:
      supplementalGroups: [100003] 5
      privileged: false
  volumes:
    - name: nfsvol
      persistentVolumeClaim:
        claimName: nfs-pvc 6
```

- The name of this pod as displayed by oc get pod.
- The image run by this pod.
- The name of the volume. This name must be the same in both the containers and volumes sections.
- The mount path as seen in the container.

- The group ID to be assigned to the container.
- 6 The PVC that was created in the previous step.

Save the pod definition to a file, for example *nfs.yaml*, and create the pod:

```
# oc create -f nfs.yaml
pod "nginx-nfs-pod" created
```

Verify that the pod was created:

```
# oc get pods

NAME READY STATUS RESTARTS AGE

nginx-nfs-pod 1/1 Running 0 4s
```

More details are shown in the oc describe pod command:

```
[root@ose70 nfs]# oc describe pod nginx-nfs-pod
Name:
        nginx-nfs-pod
Namespace: default 1
Image(s): fedora/nginx

```

The SCC used by the pod.

- The project (namespace) name.
- The supplemental group ID for the pod (all containers).
- The PVC name used by the pod.

22.2.6. Creating an Additional Pod to Reference the Same PVC

This pod definition, created in the same namespace, uses a different container. However, we can use the same backing storage by specifying the claim name in the volumes section below:

Example 22.4. Pod Object Definition

```
apiVersion: v1
kind: Pod
metadata:
  name: busybox-nfs-pod (1)
  labels:
    name: busybox-nfs-pod
spec:
 containers:
  - name: busybox-nfs-pod
    image: busybox 2
   command: ["sleep", "60000"]
    volumeMounts:
    - name: nfsvol-2 3
      mountPath: /usr/share/busybox 4
      readOnly: false
  securityContext:
    supplementalGroups: [100003] 5
    privileged: false
  volumes:
  - name: nfsvol-2
    persistentVolumeClaim:
      claimName: nfs-pvc 6
```

- The name of this pod as displayed by oc get pod.
- The image run by this pod.
- The name of the volume. This name must be the same in both the containers and volumes sections.
- The mount path as seen in the container.
- The group ID to be assigned to the container.
- 6 The PVC that was created earlier and is also being used by a different container.

Save the pod definition to a file, for example *nfs-2.yaml*, and create the pod:

```
# oc create -f nfs-2.yaml
```

```
pod "busybox-nfs-pod" created
```

Verify that the pod was created:

```
# oc get pods

NAME READY STATUS RESTARTS AGE
busybox-nfs-pod 1/1 Running 0 3s
```

More details are shown in the oc describe pod command:

```
[root@ose70 nfs]# oc describe pod busybox-nfs-pod
Name: busybox-nfs-pod
Namespace: default
Image(s): busybox
Node: ose70.rh7/192.168.234.148
Start Time: Mon, 21 Mar 2016 10:19:46 -0400
Labels: name=busybox-nfs-pod
Status: Running
Reason:
Message:
IP:
      10.1.0.5
Replication Controllers: <none>
Containers:
 busybox-nfs-pod:
   Container ID:
docker://346d432e5a4824ebf5a47fceb4247e0568ecc64eadcc160e9bab481aecfb0594
   Image: busybox
   Image ID:
docker://17583c7dd0dae6244203b8029733bdb7d17fccbb2b5d93e2b24cf48b8bfd06e2
   QoS Tier:
     cpu: BestEffort
     memory: BestEffort
   State: Running
     Started: Mon, 21 Mar 2016 10:19:48 -0400
   Ready: True
   Restart Count: 0
   Environment Variables:
Conditions:
 Type Status
 Ready True
Volumes:
 nfsvol-2:
   Type: PersistentVolumeClaim (a reference to a PersistentVolumeClaim in
the same namespace)
   ClaimName: nfs-pvc
   ReadOnly: false
  default-token-32d2z:
   Type: Secret (a secret that should populate this volume)
   SecretName: default-token-32d2z
Events:
 FirstSeen LastSeen Count From SubobjectPath
                                                  Reason Message
  4m 4m 1 {scheduler } Scheduled Successfully assigned busybox-
nfs-pod to ose70.rh7
  4m 4m 1 {kubelet ose70.rh7} implicitly required container POD Pulled
```

Container image "openshift3/ose-pod:v3.1.0.4" already present on machine 4m 4m 1 {kubelet ose70.rh7} implicitly required container POD Created Created with docker id 249b7d7519b1

4m 4m 1 {kubelet ose70.rh7} implicitly required container POD Started Started with docker id 249b7d7519b1

4m 4m 1 {kubelet ose70.rh7} spec.containers{busybox-nfs-pod} Pulled Container image "busybox" already present on machine

4m 4m 1 {kubelet ose70.rh7} spec.containers{busybox-nfs-pod} Created Created with docker id 346d432e5a48

4m 4m 1 {kubelet ose70.rh7} spec.containers{busybox-nfs-pod} Started Started with docker id 346d432e5a48

As you can see, both containers are using the same storage claim that is attached to the same NFS mount on the back end.

22.3. COMPLETE EXAMPLE USING CEPH RBD

22.3.1. Overview

This topic provides an end-to-end example of using an existing Ceph cluster as an OpenShift Container Platform persistent store. It is assumed that a working Ceph cluster is already set up. If not, consult the Overview of Red Hat Ceph Storage .

Persistent Storage Using Ceph Rados Block Device provides an explanation of persistent volumes (PVs), persistent volume claims (PVcs), and using Ceph RBD as persistent storage.

NOTE

All oc ... commands are executed on the OpenShift Container Platform master host.

22.3.2. Installing the ceph-common Package

The ceph-common library must be installed on all schedulable OpenShift Container Platform nodes:

NOTE

The OpenShift Container Platform all-in-one host is not often used to run pod workloads and, thus, is not included as a schedulable node.

yum install -y ceph-common

22.3.3. Creating the Ceph Secret

The **ceph auth get-key** command is run on a Ceph **MON** node to display the key value for the **client.admin** user:

Example 22.5. Ceph Secret Definition

apiVersion: v1 kind: Secret metadata:

```
name: ceph-secret
data:
   key: QVFB0FF2SlZheUJQRVJBQWgvS2cwT1laQUhPQno3akZwekxxdGc9PQ== 1
```

This base64 key is generated on one of the Ceph MON nodes using the ceph auth get-key client.admin | base64 command, then copying the output and pasting it as the secret key's value.

Save the secret definition to a file, for example *ceph-secret.yaml*, then create the secret:

```
$ oc create -f ceph-secret.yaml
secret "ceph-secret" created
```

Verify that the secret was created:

```
# oc get secret ceph-secret
NAME TYPE DATA AGE
ceph-secret Opaque 1 23d
```

22.3.4. Creating the Persistent Volume

Next, before creating the PV object in OpenShift Container Platform, define the persistent volume file:

Example 22.6. Persistent Volume Object Definition Using Ceph RBD

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: ceph-pv
spec:
  capacity:
    storage: 2Gi
  accessModes:
    - ReadWriteOnce
  rbd:
    monitors:
      - 192.168.122.133:6789
    pool: rbd
    image: ceph-image
    user: admin
    secretRef:
      name: ceph-secret
    fsType: ext4
    readOnly: false
  persistentVolumeReclaimPolicy: Recycle
```

- The name of the PV, which is referenced in pod definitions or displayed in various oc volume commands.
- The amount of storage allocated to this volume.

- accessModes are used as labels to match a PV and a PVC. They currently do not define any form of access control. All block storage is defined to be single user (non-shared storage).
- This defines the volume type being used. In this case, the **rbd** plug-in is defined.
- This is an array of Ceph monitor IP addresses and ports.
- This is the Ceph secret, defined above. It is used to create a secure connection from OpenShift Container Platform to the Ceph server.
- 7 This is the file system type mounted on the Ceph RBD block device.

Save the PV definition to a file, for example *ceph-pv.yaml*, and create the persistent volume:

```
# oc create -f ceph-pv.yaml
persistentvolume "ceph-pv" created
```

Verify that the persistent volume was created:

```
# oc get pv
NAME LABELS CAPACITY ACCESSMODES STATUS
CLAIM REASON AGE
ceph-pv < none> 2147483648 RWO Available
2s
```

22.3.5. Creating the Persistent Volume Claim

A persistent volume claim (PVC) specifies the desired access mode and storage capacity. Currently, based on only these two attributes, a PVC is bound to a single PV. Once a PV is bound to a PVC, that PV is essentially tied to the PVC's project and cannot be bound to by another PVC. There is a one-to-one mapping of PVs and PVCs. However, multiple pods in the same project can use the same PVC.

Example 22.7. PVC Object Definition

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
   name: ceph-claim
spec:
   accessModes:
   - ReadWriteOnce
   resources:
    requests:
    storage: 2Gi 2
```

- As mentioned above for PVs, the accessModes do not enforce access right, but rather act as labels to match a PV to a PVC.
- 2 This claim will look for PVs offering 2Gi or greater capacity.

Save the PVC definition to a file, for example *ceph-claim.yaml*, and create the PVC:

```
# oc create -f ceph-claim.yaml
persistentvolumeclaim "ceph-claim" created
#and verify the PVC was created and bound to the expected PV:
# oc get pvc
NAME
             LABELS
                       STATUS
                                  VOLUME
                                            CAPACITY
                                                       ACCESSMODES
                                                                     AGE
ceph-claim
             <none>
                       Bound
                                  ceph-pv
                                                       RWX
                                                                      21s
```

the claim was bound to the ceph-pv PV.

22.3.6. Creating the Pod

A pod definition file or a template file can be used to define a pod. Below is a pod specification that creates a single container and mounts the Ceph RBD volume for read-write access:

Example 22.8. Pod Object Definition

```
apiVersion: v1
kind: Pod
metadata:
  name: ceph-pod1
spec:
  containers:
  - name: ceph-busybox
    image: busybox
    command: ["sleep", "60000"]
    volumeMounts:
    - name: ceph-vol1
      mountPath: /usr/share/busybox 4
      readOnly: false
  volumes:
                            5
  - name: ceph-vol1
    persistentVolumeClaim:
      claimName: ceph-claim 6
```

- The name of this pod as displayed by oc get pod.
- The image run by this pod. In this case, we are telling **busybox** to sleep.
- The name of the volume. This name must be the same in both the containers and volumes sections.
- The mount path as seen in the container.
- The PVC that is bound to the Ceph RBD cluster.

Save the pod definition to a file, for example *ceph-pod1.yaml*, and create the pod:

```
# oc create -f ceph-pod1.yaml
pod "ceph-pod1" created

#verify pod was created
# oc get pod
NAME READY STATUS RESTARTS AGE
ceph-pod1 1/1 Running 0 2m
```

After a minute or so, the pod will be in the Running state.

22.3.7. Defining Group and Owner IDs (Optional)

When using block storage, such as Ceph RBD, the physical block storage is **managed** by the pod. The group ID defined in the pod becomes the group ID of **both** the Ceph RBD mount inside the container, and the group ID of the actual storage itself. Thus, it is usually unnecessary to define a group ID in the pod specifiation. However, if a group ID is desired, it can be defined using **fsGroup**, as shown in the following pod definition fragment:

Example 22.9. Group ID Pod Definition

```
spec:
  containers:
    - name:
    ...
  securityContext: 1
    fsGroup: 7777 2
```

- securityContext must be defined at the pod level, not under a specific container.
- All containers in the pod will have the same fsGroup ID.

22.3.8. Setting ceph-user-secret as Default for Projects

If you would like to make the persistent storage available to every project you have to modify the default project template. You can read more on modifying the default project template. Read more on modifying the default project template. Adding this to your default project template allows every user who has access to create a project access to the Ceph cluster.

Example 22.10. Default Project Example

```
...
apiVersion: v1
kind: Template
metadata:
    creationTimestamp: null
    name: project-request
objects:
```

```
apiVersion: v1
  kind: Project
 metadata:
    annotations:
     openshift.io/description: ${PROJECT_DESCRIPTION}
     openshift.io/display-name: ${PROJECT_DISPLAYNAME}
      openshift.io/requester: ${PROJECT_REQUESTING_USER}
    creationTimestamp: null
    name: ${PROJECT_NAME}
  spec: {}
  status: {}
- apiVersion: v1
 kind: Secret
 metadata:
    name: ceph-user-secret
    key: yoursupersecretbase64keygoeshere 1
  type:
    kubernetes.io/rbd
```

Place your super secret Ceph user key here in base64 format. See Creating the Ceph Secret.

22.4. COMPLETE EXAMPLE USING CEPH RBD FOR DYNAMIC PROVISIONING

22.4.1. Overview

This topic provides an end-to-end example of using an existing Ceph cluster as an OpenShift Container Platform dynamic persistent store. It is assumed that a working Ceph cluster is already set up. If not, consult the Overview of Red Hat Ceph Storage .

Persistent Storage Using Ceph Rados Block Device provides an explanation of persistent volumes (PVs), persistent volume claims (PVCs), and how to use Ceph Rados Block Device (RBD) as persistent storage.

NOTE

All oc ... commands are executed on the OpenShift Container Platform master host.

22.4.2. Installing the ceph-common Package

The ceph-common library must be installed on all schedulable OpenShift Container Platform nodes:

NOTE

The OpenShift Container Platform all-in-one host is not often used to run pod workloads and, thus, is not included as a schedulable node.

yum install -y ceph-common

22.4.3. Create Pool for Dynamic Volumes

It is recommended that you create a pool for your dynamic volumes to live in.

NOTE

Using the default pool of RBD is an option, but not recommended.

From a Ceph administrator or MON node, create a new pool for dynamic volumes:

```
$ ceph osd pool create kube 1024
$ ceph auth get-or-create client.kube mon 'allow r' osd 'allow class-read
object_prefix rbd_children, allow rwx pool=kube' -o
ceph.client.kube.keyring
```

22.4.4. Creating the Ceph Secret

 Run the ceph auth get-key command on a Ceph MON node to display the key value for the client.admin user:

Ceph Secret Definition

```
apiVersion: v1
kind: Secret
metadata:
  name: ceph-secret
  namespace: kube-system
data:
  key: QVFB0FF2SlZheUJQRVJBQWgvS2cwT1laQUhPQno3akZwekxxdGc9PQ== 1
type:
  kubernetes.io/rbd 2
```

- This base64 key is generated on one of the Ceph MON nodes using the ceph auth getkey client.admin | base64 command, then copying the output and pasting it as the secret key's value.
- 2 This is required for Ceph RBD to work with dynamic provisioning.
- 2. Save the secret definition to a file, for example *ceph-secret.yaml*, then create the secret:

```
$ oc create -f ceph-secret.yaml
secret "ceph-secret" created
```

3. Verify that the secret was created:

22.4.5. Creating the Ceph User Secret

1. Run the ceph auth get-key command on a Ceph MON node to display the key value for the client.kube user:

Ceph Secret Definition

```
apiVersion: v1
kind: Secret
metadata:
   name: ceph-user-secret
   namespace: default
data:
   key: QVFCbEV40VpmaGJtQ0JBQW55d2Z0NHZtcS96cE42SW1JVUQvekE9PQ== 1
type:
   kubernetes.io/rbd 2
```

- This base64 key is generated on one of the Ceph MON nodes using the ceph auth getkey client.kube | base64 command, then copying the output and pasting it as the secret key's value.
- This is required for Ceph RBD to work with dynamic provisioning.
- 2. Save the secret definition to a file, for example *ceph-user-secret.yaml*, then create the secret:

```
$ oc create -f ceph-user-secret.yaml
secret "ceph-user-secret" created
```

3. Verify that the secret was created:

```
# oc get secret ceph-user-secret

NAME TYPE DATA AGE

ceph-user-secret kubernetes.io/rbd 1 5d
```

22.4.5.1. Ceph RBD Dynamic Storage Class

1. Create a storage class to for your dynamic volumes.

ceph-storageclass.yaml

pool: kube 5
userId: kube 6

userSecretName: ceph-secret-user 7

- Ceph monitors, comma delimited. It is required.
- Ceph client ID that is capable of creating images in the pool. Default is admin.
- 3 Secret Name for adminId. It is required. The provided secret must have type kubernetes.io/rbd.
- The namespace for adminSecret. Default is default.
- Ceph RBD pool. Default is rbd, but that value is not recommended.
- Ceph client ID that is used to map the Ceph RBD image. Default is the same as adminId.
- The name of Ceph Secret for userId to map Ceph RBD image. It must exist in the same namespace as PVCs. It is required unless its set as the default in new projects.

22.4.6. Creating the Persistent Volume Claim

A persistent volume claim (PVC) specifies the desired access mode and storage capacity. Currently, based on only these two attributes, a PVC is bound to a single PV. Once a PV is bound to a PVC, that PV is essentially tied to the PVC's project and cannot be bound to by another PVC. There is a one-to-one mapping of PVs and PVCs. However, multiple pods in the same project can use the same PVC.

PVC Object Definition

kind: PersistentVolumeClaim

apiVersion: v1

metadata:

name: ceph-claim

spec:

accessModes:

1

- ReadWriteOnce

resources: requests:

storage: 2Gi 2

- As mentioned above for PVs, the accessModes do not enforce access right, but rather act as labels to match a PV to a PVC.
- This claim will look for PVs offering 2Gi or greater capacity.
 - 1. Save the PVC definition to a file, for example *ceph-claim.yaml*, and create the PVC:

```
# oc create -f ceph-claim.yaml
persistentvolumeclaim "ceph-claim" created

#and verify the PVC was created and bound to the expected PV:
# oc get pvc
NAME STATUS VOLUME
```

```
CAPACITY ACCESSMODES AGE
ceph-claim Bound pvc-f548d663-3cac-11e7-9937-0024e8650c7a
2Gi RWO 1m
```

the claim dynamically created a Ceph RBD PV.

22.4.7. Creating the Pod

A pod definition file or a template file can be used to define a pod. Below is a pod specification that creates a single container and mounts the Ceph RBD volume for read-write access:

Pod Object Definition

```
apiVersion: v1
kind: Pod
metadata:
  name: ceph-pod1
spec:
  containers:
  - name: ceph-busybox
    image: busybox
    command: ["sleep", "60000"]
    volumeMounts:
    - name: ceph-vol1
      mountPath: /usr/share/busybox 4
      readOnly: false
  volumes:
  - name: ceph-vol1
    persistentVolumeClaim:
      claimName: ceph-claim 6
```

- The name of this pod as displayed by oc get pod.
- The image run by this pod. In this case, we are telling busybox to sleep.
- The name of the volume. This name must be the same in both the containers and volumes sections.
- The mount path as seen in the container.
- 6 The PVC that is bound to the Ceph RBD cluster.
 - 1. Save the pod definition to a file, for example ceph-pod1.yaml, and create the pod:

```
# oc create -f ceph-pod1.yaml
pod "ceph-pod1" created

#verify pod was created
# oc get pod
NAME READY STATUS RESTARTS AGE
ceph-pod1 1/1 Running 0 2m
```

After approximately a minute, the pod will be in the Running state.

22.4.8. Setting ceph-user-secret as Default for Projects

If you want to make the persistent storage available to every project, you must modify the default project template. Read more on modifying the default project template. Adding this to your default project template allows every user who has access to create a project access to the Ceph cluster.

Default Project Example

```
apiVersion: v1
kind: Template
metadata:
  creationTimestamp: null
  name: project-request
objects:
- apiVersion: v1
  kind: Project
  metadata:
    annotations:
      openshift.io/description: ${PROJECT_DESCRIPTION}
      openshift.io/display-name: ${PROJECT_DISPLAYNAME}
      openshift.io/requester: ${PROJECT_REQUESTING_USER}
    creationTimestamp: null
    name: ${PROJECT_NAME}
  spec: {}
  status: {}
- apiVersion: v1
  kind: Secret
  metadata:
    name: ceph-user-secret
  data:
    key: QVFCbEV40VpmaGJtQ0JBQW55d2Z0NHZtcS96cE42SW1JVUQvekE9PQ== 1
    kubernetes.io/rbd
```

Place the key from ceph-user-secret here in base64 format. See Creating the Ceph Secret.

22.5. COMPLETE EXAMPLE USING GLUSTERFS

22.5.1. Overview

This topic provides an end-to-end example of how to use an existing Gluster cluster as an OpenShift Container Platform persistent store. It is assumed that a working Gluster cluster is already set up. If not, consult the Red Hat Gluster Storage Administration Guide .

Persistent Storage Using GlusterFS provides an explanation of persistent volumes (PVs), persistent volume claims (PVCs), and using GlusterFS as persistent storage.

For an end-to-end example of how to dynamically provision GlusterFS volumes, see Complete Example of Dynamic Provisioning Using GlusterFS. The persistent volume (PV) and endpoints are both created dynamically by GlusterFS.

NOTE

All oc ... commands are executed on the OpenShift Container Platform master host.

22.5.2. Installing the glusterfs-fuse Package

The glusterfs-fuse library must be installed on all schedulable OpenShift Container Platform nodes:

```
# yum install -y glusterfs-fuse
```

NOTE

The OpenShift Container Platform all-in-one host is often not used to run pod workloads and, thus, is not included as a schedulable node.

22.5.3. Creating the Gluster Endpoints and Gluster Service for Persistence

The named endpoints define each node in the Gluster-trusted storage pool:

Example 22.11. GlusterFS Endpoint Definition

```
apiVersion: v1
kind: Endpoints
metadata:
   name: gluster-cluster 1
subsets:
- addresses:
- ip: 192.168.122.21
ports:
- port: 1
   protocol: TCP
- addresses:
- ip: 192.168.122.22
ports:
- port: 1
   protocol: TCP
```

- The endpoints name. If using a service, then the endpoints name must match the service name.
- An array of IP addresses for each node in the Gluster pool. Currently, host names are not supported.
- The port numbers are ignored, but must be legal port numbers. The value 1 is commonly used.

Save the endpoints definition to a file, for example *gluster-endpoints.yaml*, then create the endpoints object:

```
# oc create -f gluster-endpoints.yaml
endpoints "gluster-cluster" created
```

Verify that the endpoints were created:

NOTE

To persist the Gluster endpoints, you also need to create a service.

NOTE

Endpoints are name-spaced. Each project accessing the Gluster volume needs its own endpoints.

Example 22.12. GlusterFS Service Definition

```
apiVersion: v1
kind: Service
metadata:
   name: gluster-cluster 1
spec:
   ports:
   - port: 1 2
```

- The name of the service. If using a service, then the endpoints name must match the service name.
- The port should match the same port used in the endpoints.

Save the service definition to a file, for example gluster-service.yaml, then create the endpoints object:

```
# oc create -f gluster-service.yaml
endpoints "gluster-cluster" created
```

Verify that the service was created:

```
# oc get service gluster-cluster

NAME CLUSTER-IP EXTERNAL-IP PORT(S) AGE
gluster-cluster 10.0.0.130 <none> 1/TCP 9s
```

22.5.4. Creating the Persistent Volume

Next, before creating the PV object, define the persistent volume in OpenShift Container Platform:

Persistent Volume Object Definition Using GlusterFS

- The name of the PV, which is referenced in pod definitions or displayed in various oc volume commands.
- The amount of storage allocated to this volume.
- accessModes are used as labels to match a PV and a PVC. They currently do not define any form of access control.
- This defines the volume type being used. In this case, the glusterfs plug-in is defined.
- This references the endpoints named above.
- This is the Gluster volume name, preceded by /.
- The volume reclaim policy Retain indicates that the volume will be preserved after the pods accessing it terminates. For GlusterFS, the accepted values include Retain, and Delete.

Save the PV definition to a file, for example *gluster-pv.yaml*, and create the persistent volume:

```
# oc create -f gluster-pv.yaml
persistentvolume "gluster-pv" created
```

Verify that the persistent volume was created:

```
# oc get pv
NAME LABELS CAPACITY ACCESSMODES STATUS CLAIM
REASON AGE
gluster-pv <none> 1Gi RWX Available
37s
```

22.5.5. Creating the Persistent Volume Claim

A persistent volume claim (PVC) specifies the desired access mode and storage capacity. Currently, based on only these two attributes, a PVC is bound to a single PV. Once a PV is bound to a PVC, that PV is essentially tied to the PVC's project and cannot be bound to by another PVC. There is a one-to-one mapping of PVs and PVCs. However, multiple pods in the same project can use the same PVC.

Example 22.13. PVC Object Definition

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
   name: gluster-claim 1
spec:
   accessModes:
   - ReadWriteMany
   resources:
      requests:
      storage: 1Gi 3
```

- The claim name is referenced by the pod under its volumes section.
- As mentioned above for PVs, the accessModes do not enforce access rights, but rather act as labels to match a PV to a PVC.
- This claim will look for PVs offering 1Gi or greater capacity.

Save the PVC definition to a file, for example gluster-claim.yaml, and create the PVC:

```
# oc create -f gluster-claim.yaml
persistentvolumeclaim "gluster-claim" created
```

Verify the PVC was created and bound to the expected PV:

```
# oc get pvc
NAME LABELS STATUS VOLUME CAPACITY ACCESSMODES
AGE
gluster-claim <none> Bound gluster-pv 1Gi RWX
24s
```

The claim was bound to the gluster-pv PV.

22.5.6. Defining GlusterFS Volume Access

Access is necessary to a node in the Gluster-trusted storage pool. On this node, examine the **glusterfs-fuse** mount:

The owner has ID 592.

The group has ID 590.

In order to access the **HadoopVol** volume, the container must match the SELinux label, and either run with a UID of 592, or with 590 in its supplemental groups. It is recommended to gain access to the volume by matching the Gluster mount's groups, which is defined in the pod definition below.

By default, SELinux does not allow writing from a pod to a remote Gluster server. To enable writing to GlusterFS volumes with SELinux enforcing on each node, run:

```
# setsebool -P virt_sandbox_use_fusefs on
```

NOTE

The virt_sandbox_use_fusefs boolean is defined by the docker-selinux package. If you get an error saying it is not defined, ensure that this package is installed.

22.5.7. Creating the Pod using NGINX Web Server image

A pod definition file or a template file can be used to define a pod. Below is a pod specification that creates a single container and mounts the Gluster volume for read-write access:

NOTE

The NGINX image may require to run in privileged mode to create the mount and run properly. An easy way to accomplish this is to simply add your user to the **privileged** Security Context Constraint (SCC):

\$ oc adm policy add-scc-to-user privileged myuser

Then, add the **privileged**: **true** to the containers **securityContext**: section of the YAML file (as seen in the example below).

Managing Security Context Constraints provides additional information regarding SCCs.

Example 22.14. Pod Object Definition using NGINX image

```
apiVersion: v1
kind: Pod
metadata:
  name: gluster-pod1
  labels:
    name: gluster-pod1
spec:
  containers:
  - name: gluster-pod1
    image: nginx
    ports:
    - name: web
      containerPort: 80
    securityContext:
      privileged: true
    volumeMounts:
```

- name: gluster-vol1 3
mountPath: /usr/share/nginx/html 4

readOnly: false
securityContext:

supplementalGroups: [590] 5

volumes:

name: gluster-vol1 6 persistentVolumeClaim:

claimName: gluster-claim 7

- The name of this pod as displayed by oc get pod.
- The image run by this pod. In this case, we are using a standard NGINX image.
- The name of the volume. This name must be the same in both the containers and volumes sections.
- The mount path as seen in the container.
- The SupplementalGroup ID (Linux Groups) to be assigned at the pod level and as discussed this should match the POSIX permissions on the Gluster volume.
- The PVC that is bound to the Gluster cluster.

Save the pod definition to a file, for example *gluster-pod1.yaml*, and create the pod:

```
# oc create -f gluster-pod1.yaml
pod "gluster-pod1" created
```

Verify the pod was created:

oc get pod
NAME READY STATUS RESTARTS AGE
gluster-pod1 1/1 Running 0 31s

1

After a minute or so, the pod will be in the **Running** state.

More details are shown in the oc describe pod command:

oc describe pod gluster-pod1

Name: gluster-pod1
Namespace: default 1
Security Policy: privileged
Node: ose1.rhs/192.168.122.251

Start Time: Wed, 24 Aug 2016 12:37:45 -0400

Labels: name=gluster-pod1

Status: Running
IP: 172.17.0.2 2
Controllers: <none>

```
Containers:
 gluster-pod1:
   Container ID:
docker://e67ed01729e1dc7369c5112d07531a27a7a02a7eb942f17d1c5fce32d8c31a2d

- The SCC used by the pod.
- The project (namespace) name.
- The security context level requested, in this case privileged
- The supplemental group ID for the pod (all containers).
- The PVC name used by the pod.

22.6. COMPLETE EXAMPLE OF DYNAMIC PROVISIONING USING CONTAINERIZED GLUSTERFS

22.6.1. Overview

NOTE

This example assumes a functioning OpenShift Container Platform cluster along with Heketi and GlusterFS. All oc commands are executed on the OpenShift Container Platform master host.

This topic provides an end-to-end example of how to dynamically provision GlusterFS volumes. In this example, a simple NGINX HelloWorld application is deployed using the Red Hat Container Native Storage (CNS) solution. CNS hyper-converges GlusterFS storage by containerizing it into the OpenShift Container Platform cluster.

The Red Hat Gluster Storage Administration Guide can also provide additional information about GlusterFS.

To get started, follow the gluster-kubernetes quickstart guide for an easy Vagrant-based installation and deployment of a working OpenShift Container Platform cluster with Heketi and GlusterFS containers.

22.6.2. Verify the Environment and Gather Needed Information

NOTE

At this point, there should be a working OpenShift Container Platform cluster deployed, and a working Heketi server with GlusterFS.

1. Verify and view the cluster environment, including nodes and pods:

```
$ oc get nodes,pods
NAME
          STATUS
                    AGE
          Ready
                    22h
master
node0
          Ready
                    22h
node1
          Ready
                    22h
node2
                    22h
          Ready
NAME
                                    READY
                                              STATUS
RESTARTS
           AGE
                         1/1
                                    Running
                                                        0
1d
glusterfs-node0-2509304327-vpce1
                                    1/1
                                              Running
                                                        0
          192.168.10.100
glusterfs-node1-3290690057-hhq92
                                    1/1
                                              Running
          192.168.10.101
                           node1 1
glusterfs-node2-4072075787-okzjv
                                    1/1
                                              Running
                                                        0
          192.168.10.102
                           node2
heketi-3017632314-yyngh
                                    1/1
                                              Running
1d
          10.42.0.0
                           node0 2
```

- Example of GlusterFS storage pods running. There are three in this example.
- Heketi server pod.
- 2. If not already set in the environment, export the **HEKETI_CLI_SERVER**:

```
$ export HEKETI_CLI_SERVER=$(oc describe svc/heketi | grep
"Endpoints:" | awk '{print "http://"$2}')
```

3. Identify the Heketi REST URL and server IP address:

```
$ echo $HEKETI_CLI_SERVER
http://10.42.0.0:8080
```

4. Identify the Gluster endpoints that are needed to pass in as a parameter into the storage class, which is used in a later step (heketi-storage-endpoints).

```
$ oc get endpoints

NAME ENDPOINTS

AGE

heketi 10.42.0.0:8080

22h

heketi-storage-endpoints

192.168.10.100:1,192.168.10.101:1,192.168.10.102:1 22h

kubernetes 192.168.10.90:6443

23h
```

The defined GlusterFS endpoints. In this example, they are called heketi-storage-endpoints.

NOTE

By default, user_authorization is disabled. If enabled, you may need to find the rest user and rest user secret key. (This is not applicable for this example, as any values will work).

22.6.3. Create a Storage Class for Your GlusterFS Dynamic Provisioner

Storage classes manage and enable persistent storage in OpenShift Container Platform. Below is an example of a *Storage class* requesting 5GB of on-demand storage to be used with your *HelloWorld* application.

- Name of the storage class.
- The provisioner.
- The GlusterFS-defined endpoint (oc get endpoints).
- Heketi REST URL, taken from Step 1 above (echo \$HEKETI_CLI_SERVER).
- Rest username. This can be any value since authorization is turned off.
- Rest user key. This can be any value.
 - 1. Create the Storage Class YAML file, save it, then submit it to OpenShift Container Platform:

```
$ oc create -f gluster-storage-class.yaml
storageclass "gluster-heketi" created
```

2. View the storage class:

22.6.4. Create a PVC to Request Storage for Your Application

Create a persistent volume claim (PVC) requesting 5GB of storage.
 During that time, the Dynamic Provisioning Framework and Heketi will automatically provision a new GlusterFS volume and generate the persistent volume (PV) object:

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: gluster1
  annotations:
    volume.beta.kubernetes.io/storage-class: gluster-heketi
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
    storage: 5Gi 2
```

- The Kubernetes storage class annotation and the name of the storage class.
- The amount of storage requested.
 - 1. Create the PVC YAML file, save it, then submit it to OpenShift Container Platform:

```
$ oc create -f gluster-pvc.yaml
persistentvolumeclaim "gluster1" created
```

2. View the PVC:

```
$ oc get pvc
NAME STATUS VOLUME
CAPACITY ACCESSMODES AGE
gluster1 Bound pvc-7d37c7bd-bb5b-11e6-b81e-525400d87180 5Gi
RWO 14h
```

Notice that the PVC is bound to a dynamically created volume.

3. View the persistent volume (PV):

```
$ oc get pv

NAME CAPACITY ACCESSMODES

RECLAIMPOLICY STATUS CLAIM REASON AGE
```

pvc-7d37c7bd-bb5b-11e6-b81e-525400d87180 5Gi RWO
Delete Bound default/gluster1 14h

22.6.5. Create a NGINX Pod That Uses the PVC

At this point, you have a dynamically created GlusterFS volume, bound to a PVC. Now, you can use this claim in a pod. Create a simple NGINX pod:

```
apiVersion: v1
kind: Pod
metadata:
 name: nginx-pod
  labels:
    name: nginx-pod
spec:
  containers:
  - name: nginx-pod
    image: gcr.io/google_containers/nginx-slim:0.8
    ports:
    - name: web
      containerPort: 80
    securityContext:
      privileged: true
    volumeMounts:
    - name: gluster-vol1
      mountPath: /usr/share/nginx/html
  volumes:
  - name: gluster-vol1
    persistentVolumeClaim:
      claimName: gluster1 (1)
```

- The name of the PVC created in the previous step.
 - 1. Create the Pod YAML file, save it, then submit it to OpenShift Container Platform:

```
$ oc create -f nginx-pod.yaml
pod "gluster-pod1" created
```

2. View the pod:

\$ oc get	pods -o wide				
NAME			READY	STATUS	RESTARTS
AGE	IP	NODE			
nginx-po	d		1/1	Running	0
9m	10.38.0.0	node1			
glusterf	s-node0-2509304327	'-vpce1	1/1	Running	0
1 d	192.168.10.100	node0			
glusterf	s-node1-3290690057	'-hhq92	1/1	Running	0
1 d	192.168.10.101	node1			
glusterf	s-node2-4072075787	-okzjv	1/1	Running	0
1 d	192.168.10.102	node2			
heketi-3	917632314-yyngh		1/1	Running	0
1d	10.42.0.0	node0			

NOTE

This may take a few minutes, as the the pod may need to download the image if it does not already exist.

3. oc exec into the container and create an *index.html* file in the mountPath definition of the pod:

```
$ oc exec -ti nginx-pod /bin/sh
$ cd /usr/share/nginx/html
$ echo 'Hello World from GlusterFS!!!' > index.html
$ ls
index.html
$ exit
```

4. Using the curl command from the master node, curl the URL of the pod:

```
$ curl http://10.38.0.0
Hello World from GlusterFS!!!
```

5. Check your Gluster pod to ensure that the *index.html* file was written. Choose any of the Gluster pods:

```
$ oc exec -ti glusterfs-node1-3290690057-hhq92 /bin/sh
$ mount | grep heketi
/dev/mapper/VolGroup00-LogVol00 on /var/lib/heketi type xfs
(rw, relatime, seclabel, attr2, inode64, noquota)
/dev/mapper/vg_f92e09091f6b20ab12b02a2513e4ed90-
brick_1e730a5462c352835055018e1874e578 on
/var/lib/heketi/mounts/vg_f92e09091f6b20ab12b02a2513e4ed90/brick_1e7
30a5462c352835055018e1874e578 type xfs
(rw, noatime, seclabel, nouuid, attr2, inode64, logbsize=256k, sunit=512, sw
idth=512, noquota)
/dev/mapper/vg_f92e09091f6b20ab12b02a2513e4ed90-
brick_d8c06e606ff4cc29ccb9d018c73ee292 on
/var/lib/heketi/mounts/vg_f92e09091f6b20ab12b02a2513e4ed90/brick_d8c
06e606ff4cc29ccb9d018c73ee292 type xfs
(rw, noatime, seclabel, nouuid, attr2, inode64, logbsize=256k, sunit=512, sw
idth=512, noquota)
/var/lib/heketi/mounts/vg_f92e09091f6b20ab12b02a2513e4ed90/brick_d8c
06e606ff4cc29ccb9d018c73ee292/brick
$ 1s
index.html
$ cat index.html
Hello World from GlusterFS!!!
```

22.7. COMPLETE EXAMPLE OF DYNAMIC PROVISIONING USING DEDICATED GLUSTERFS

22.7.1. Overview

NOTE

This example assumes a functioning OpenShift Container Platform cluster along with Heketi and GlusterFS. All oc commands are executed on the OpenShift Container Platform master host.

Container Native Storage (CNS) using GlusterFS and Heketi is a great way to perform dynamic provisioning for shared filesystems in a Kubernetes-based cluster like OpenShift Container Platform. However, if an existing, dedicated Gluster cluster is available external to the OpenShift Container Platform cluster, you can also provision storage from it rather than a containerized GlusterFS implementation.

This example:

- Shows how simple it is to install and configure a Heketi server to work with OpenShift Container Platform to perform dynamic provisioning.
- Assumes some familiarity with Kubernetes and the Kubernetes Persistent Storage model.
- Assumes you have access to an existing, dedicated GlusterFS cluster that has raw devices
 available for consumption and management by a Heketi server. If you do not have this, you can
 create a three node cluster using your virtual machine solution of choice. Ensure sure you
 create a few raw devices and give plenty of space (at least 100GB recommended). See Red Hat
 Gluster Storage Installation Guide.

22.7.2. Environment and Prerequisites

This example uses the following environment and prerequisites:

- GlusterFS cluster running Red Hat Gluster Storage (RHGS) 3.1. Three nodes, each with at least two 100GB RAW devices:
 - o gluster23.rhs (192.168.1.200)
 - o gluster24.rhs (192.168.1.201)
 - o gluster25.rhs (192.168.1.202)
- Heketi service/client node running Red Hat Enterprise Linux (RHEL) 7.x or RHGS 3.1. Heketi can be installed on one of the Gluster nodes:
 - o glusterclient2.rhs (192.168.1.203)
- OpenShift Container Platform node. This example uses an all-in-one OpenShift Container
 Platform cluster (master and node on a single host), though it can work using a standard, multinode cluster as well.
 - o k8dev2.rhs (192.168.1.208)

22.7.3. Installing and Configuring Heketi

Heketi is used to manage the Gluster cluster storage (adding volumes, removing volumes, etc.). As stated, this can be RHEL or RHGS, and can be installed on one of the existing Gluster storage nodes. This example uses a stand-alone RHGS 3.1 node running Heketi.

The Red Hat Gluster Storage Administration Guide can be used a reference during this process.

1. Install Heketi and the Heketi client. From the host designated to run Heketi and the Heketi client, run:

```
# yum install heketi heketi-client -y
```

NOTE

The Heketi server can be any of the existing hosts, though typically this will be the OpenShift Container Platform master host. This example, however, uses a separate host not part of the GlusterFS or OpenShift Container Platform cluster.

2. Create and install Heketi private keys on each GlusterFS cluster node. From the host that is running Heketi:

```
# ssh-keygen -f /etc/heketi/heketi_key -t rsa -N ''
# ssh-copy-id -i /etc/heketi/heketi_key.pub root@gluster23.rhs
# ssh-copy-id -i /etc/heketi/heketi_key.pub root@gluster24.rhs
# ssh-copy-id -i /etc/heketi/heketi_key.pub root@gluster25.rhs
# chown heketi:heketi /etc/heketi/heketi_key*
```

3. Edit the /usr/share/heketi/heketi.json file to setup the SSH executor. Below is an excerpt from the /usr/share/heketi/heketi.json file; the parts to configure are the executor and SSH sections:

```
"executor": "ssh", 1

"_sshexec_comment": "SSH username and private key file
information",
    "sshexec": {
        "keyfile": "/etc/heketi/heketi_key", 2
        "user": "root", 3
        "port": "22", 4
        "fstab": "/etc/fstab" 5
},
```

- 1 Change executor from mock to ssh.
- 2 Add in the public key directory specified in previous step.
- Update user to a user that has sudo or root access.
- 4 Set port to 22 and remove all other text.
- Set fstab to the default, /etc/fstab and remove all other text.
- 4. Restart and enable service:

```
# systemctl restart heketi
# systemctl enable heketi
```

5. Test the connection to Heketi:

```
# curl http://glusterclient2.rhs:8080/hello
Hello from Heketi
```

6. Set an environment variable for the Heketi server:

```
# export HEKETI_CLI_SERVER=http://glusterclient2.rhs:8080
```

22.7.4. Loading Topology

Topology is used to tell Heketi about the environment and what nodes and devices it will manage.

NOTE

Heketi is currently limited to managing raw devices only. If a device is already a Gluster volume, it will be skipped and ignored.

1. Create and load the topology file. There is a sample file located in /usr/share/heketi/toplogy-sample.json by default, or /etc/heketi depending on how it was installed.

```
"clusters": [
    "nodes": [
      {
        "node": {
          "hostnames": {
            "manage": [
               "gluster23.rhs"
            "storage": [
               "192.168.1.200"
            ]
          "zone": 1
        },
        "devices": [
          "/dev/sde",
          "/dev/sdf"
      },
        "node": {
          "hostnames": {
            "manage": [
               "gluster24.rhs"
            "storage": [
               "192.168.1.201"
          },
          "zone": 1
        "devices": [
          "/dev/sde",
```

```
"/dev/sdf"
        },
        {
          "node": {
            "hostnames": {
               "manage": [
                 "gluster25.rhs"
               "storage": [
                "192.168.1.202"
            "zone": 1
          "devices": [
            "/dev/sde",
            "/dev/sdf"
        },
      1
    }
  ]
}
```

2. Using heketi-cli, run the following command to load the topology of your environment.

```
# heketi-cli topology load --json=topology.json

Found node gluster23.rhs on cluster
bdf9d8ca3fa269ff89854faf58f34b9a
   Adding device /dev/sde ... OK
   Adding device /dev/sdf ... OK
   Creating node gluster24.rhs ... ID:
8e677d8bebe13a3f6846e78a67f07f30
   Adding device /dev/sde ... OK
   Adding device /dev/sdf ... OK
...
```

3. Create a Gluster volume to verify Heketi:

```
# heketi-cli volume create --size=50
```

4. View the volume information from one of the the Gluster nodes:

```
# gluster volume info

Volume Name: vol_335d247ac57ecdf40ac616514cc6257f 1
Type: Distributed-Replicate
Volume ID: 75be7940-9b09-4e7f-bfb0-a7eb24b411e3
Status: Started
...
...
```

1 Volume created by heketi-cli.

22.7.5. Dynamically Provision a Volume

 Create a StorageClass object definition. The definition below is based on the minimum requirements needed for this example to work with OpenShift Container Platform. See Dynamic Provisioning and Creating Storage Classes for additional parameters and specification definitions.

```
kind: StorageClass
apiVersion: storage.k8s.io/v1beta1
metadata:
   name: gluster-dyn
provisioner: kubernetes.io/glusterfs
parameters:
   resturl: "http://glusterclient2.rhs:8080"  1
   restauthenabled: "false"  2
```

- The Heketi server from the **HEKETI_CLI_SERVER** environment variable.
- Since authentication is not turned on in this example, set to false.
- 2. From the OpenShift Container Platform master host, create the storage class:

```
# oc create -f glusterfs-storageclass1.yaml
storageclass "gluster-dyn" created
```

3. Create a persistent volume claim (PVC), requesting the newly-created storage class. For example:

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: gluster-dyn-pvc
  annotations:
    volume.beta.kubernetes.io/storage-class: gluster-dyn
spec:
  accessModes:
    - ReadWriteMany
resources:
    requests:
       storage: 30Gi
```

4. From the OpenShift Container Platform master host, create the PVC:

```
# oc create -f glusterfs-pvc-storageclass.yaml
persistentvolumeclaim "gluster-dyn-pvc" created
```

5. View the PVC to see that the volume was dynamically created and bound to the PVC:

```
# oc get pvc
NAME STATUS VOLUME
```

```
CAPACITY ACCESSMODES STORAGECLASS AGE gluster-dyn-pvc Bound pvc-78852230-d8e2-11e6-a3fa-0800279cf26f 30Gi RWX gluster-dyn 42s
```

6. Verify and view the new volume on one of the Gluster nodes:

- Volume created by heketi-cli.
- New dynamically created volume triggered by Kubernetes and the storage class.

22.7.6. Creating a NGINX Pod That Uses the PVC

At this point, you have a dynamically created GlusterFS volume bound to a PVC. You can now now utilize this PVC in a pod. In this example, create a simple NGINX pod.

1. Create the pod object definition:

```
apiVersion: v1
kind: Pod
metadata:
  name: gluster-pod1
  labels:
    name: gluster-pod1
spec:
  containers:
  - name: gluster-pod1
    image: gcr.io/google_containers/nginx-slim:0.8
    ports:
    - name: web
      containerPort: 80
    securityContext:
      privileged: true
    volumeMounts:
    - name: gluster-vol1
      mountPath: /usr/share/nginx/html
  volumes:
  - name: gluster-vol1
    persistentVolumeClaim:
      claimName: gluster-dyn-pvc 1
```

- 1
- The name of the PVC created in the previous step.
- 2. From the OpenShift Container Platform master host, create the pod:

```
# oc create -f nginx-pod.yaml
pod "gluster-pod1" created
```

3. View the pod. Give it a few minutes, as it might need to download the image if it does not already exist:

```
# oc get pods -o wide

NAME READY STATUS RESTARTS

AGE IP NODE

gluster-pod1 1/1 Running 0

9m 10.38.0.0 node1
```

4. Now remote into the container with oc exec and create an index.html file:

```
# oc exec -ti gluster-pod1 /bin/sh
$ cd /usr/share/nginx/html
$ echo 'Hello World from GlusterFS!!!' > index.html
$ ls
index.html
$ exit
```

5. Now curl the URL of the pod:

```
# curl http://10.38.0.0
Hello World from GlusterFS!!!
```

22.8. MOUNTING VOLUMES ON PRIVILEGED PODS

22.8.1. Overview

Persistent volumes can be mounted to pods with the **privileged** security context constraint (SCC) attached.

NOTE

While this topic uses GlusterFS as a sample use-case for mounting volumes onto privileged pods, it can be adapted to use any supported storage plug-in.

22.8.2. Prerequisites

- An existing Gluster volume.
- glusterfs-fuse installed on all hosts.
- Definitions for GlusterFS:
 - o Endpoints and services: gluster-endpoints-service.yaml and gluster-endpoints.yaml

- o Persistent volumes: gluster-pv.yaml
- o Persistent volume claims: gluster-pvc.yaml
- Privileged pods: gluster-nginx-pod.yaml
- A user with the cluster-admin role binding. For this guide, that user is called admin.

22.8.3. Creating the Persistent Volume

Creating the PersistentVolume makes the storage accessible to users, regardless of projects.

1. As the admin, create the service, endpoint object, and persistent volume:

```
$ oc create -f gluster-endpoints-service.yaml
$ oc create -f gluster-endpoints.yaml
$ oc create -f gluster-pv.yaml
```

2. Verify that the objects were created:

```
$ oc get svc
NAME
                  CLUSTER_IP
                                  EXTERNAL_IP
                                                 PORT(S)
                                                           SELECTOR
AGE
gluster-cluster
                  172.30.151.58
                                  <none>
                                                 1/TCP
                                                           <none>
24s
$ oc get ep
                  ENDPOINTS
                                                       AGE
NAME
gluster-cluster
                  192.168.59.102:1,192.168.59.103:1
                                                       2m
$ oc get pv
NAME
                         LABELS
                                   CAPACITY
                                               ACCESSMODES
                                                             STATUS
CLAIM
          REASON
                    AGE
gluster-default-volume
                         <none>
                                   2Gi
                                               RWX
Available
                                2d
```

22.8.4. Creating a Regular User

Adding a regular user to the **privileged** SCC (or to a group given access to the SCC) allows them to run **privileged** pods:

1. As the admin, add a user to the SCC:

```
$ oc adm policy add-scc-to-user privileged <username>
```

2. Log in as the regular user:

```
$ oc login -u <username> -p <password>
```

3. Then, create a new project:

```
$ oc new-project <project_name>
```

22.8.5. Creating the Persistent Volume Claim

1. As a regular user, create the **PersistentVolumeClaim** to access the volume:

```
$ oc create -f gluster-pvc.yaml -n project_name>
```

2. Define your pod to access the claim:

Example 22.15. Pod Definition

```
apiVersion: v1
id: gluster-nginx-pvc
kind: Pod
metadata:
  name: gluster-nginx-priv
spec:
  containers:
    - name: gluster-nginx-priv
      image: fedora/nginx
      volumeMounts:
        - mountPath: /mnt/gluster 1
          name: gluster-volume-claim
      securityContext:
        privileged: true
  volumes:
    - name: gluster-volume-claim
      persistentVolumeClaim:
        claimName: gluster-claim 2
```

- Volume mount within the pod.
- The gluster-claim must reflect the name of the PersistentVolume.
- 3. Upon pod creation, the mount directory is created and the volume is attached to that mount point.

As regular user, create a pod from the definition:

```
$ oc create -f gluster-nginx-pod.yaml
```

4. Verify that the pod created successfully:

```
$ oc get pods
NAME READY STATUS RESTARTS AGE
gluster-nginx-pod 1/1 Running 0 36m
```

It can take several minutes for the pod to create.

22.8.6. Verifying the Setup

22.8.6.1. Checking the Pod SCC

1. Export the pod configuration:

\$ oc export pod <pod_name>

2. Examine the output. Check that openshift.io/scc has the value of privileged:

Example 22.16. Export Snippet

```
metadata:
   annotations:
    openshift.io/scc: privileged
```

22.8.6.2. Verifying the Mount

1. Access the pod and check that the volume is mounted:

```
$ oc rsh <pod_name>
[root@gluster-nginx-pvc /]# mount
```

2. Examine the output for the Gluster volume:

```
Example 22.17. Volume Mount
```

```
192.168.59.102:gv0 on /mnt/gluster type fuse.gluster (rw,relatime,user_id=0,group_id=0,default_permissions,allow_other,max_read=131072)
```

22.9. BACKING DOCKER REGISTRY WITH GLUSTERFS STORAGE

22.9.1. Overview

This topic reviews how to attach a GlusterFS persistent volume to the Docker Registry.

It is assumed that the Docker registry service has already been started and the Gluster volume has been created.

22.9.2. Prerequisites

- The docker-registry was deployed without configuring storage.
- A Gluster volume exists and glusterfs-fuse is installed on schedulable nodes.
- Definitions written for GlusterFS endpoints and service, persistent volume (PV), and persistent volume claim (PVC).
 - o For this guide, these will be:
 - gluster-endpoints-service.yaml
 - gluster-endpoints.yaml
 - gluster-pv.yaml
 - gluster-pvc.yaml

- A user with the cluster-admin role binding.
 - o For this guide, that user is admin.

NOTE

All oc commands are executed on the master node as the admin user.

22.9.3. Create the Gluster Persistent Volume

First, make the Gluster volume available to the registry.

```
$ oc create -f gluster-endpoints-service.yaml
$ oc create -f gluster-endpoints.yaml
$ oc create -f gluster-pv.yaml
$ oc create -f gluster-pvc.yaml
```

Check to make sure the PV and PVC were created and bound successfully. The expected output should resemble the following. Note that the PVC status is **Bound**, indicating that it has bound to the PV.

```
$ oc get pv
NAME
             LABELS
                        CAPACITY
                                   ACCESSMODES
                                                  STATUS
                                                               CLAIM
          AGE
REASON
                                   RWX
                                                  Available
gluster-pv
             <none>
                        1Gi
37s
$ oc get pvc
NAME
                LABELS
                           STATUS
                                     VOLUME
                                                   CAPACITY
                                                               ACCESSMODES
AGE
gluster-claim
                           Bound
                                     gluster-pv
                                                               RWX
                <none>
                                                   1Gi
24s
```

NOTE

If either the PVC or PV failed to create or the PVC failed to bind, refer back to the GlusterFS Persistent Storage guide. Do not proceed until they initialize and the PVC status is **Bound**.

22.9.4. Attach the PVC to the Docker Registry

Before moving forward, ensure that the docker-registry service is running.

\$ oc get svc			
NAME	CLUSTER_IP	EXTERNAL_IP	PORT(S)
SELECTOR	AGE		
docker-registry	172.30.167.194	<none></none>	5000/TCP
docker-registry=d	default 18m		

NOTE

If either the **docker-registry** service or its associated pod is not running, refer back to the **docker-registry** setup instructions for troubleshooting before continuing.

Then, attach the PVC:

```
$ oc volume deploymentconfigs/docker-registry --add --name=v1 -t pvc \
     --claim-name=gluster-claim --overwrite
```

Deploying a Docker Registry provides more information on using the Docker registry.

22.9.5. Known Issues

22.9.5.1. Pod Cannot Resolve the Volume Host

In non-production cases where the **dnsmasq** server is located on the same node as the OpenShift Container Platform master service, pods might not resolve to the host machines when mounting the volume, causing errors in the **docker-registry-1-deploy** pod. This can happen when **dnsmasq.service** fails to start because of a collision with OpenShift Container Platform DNS on port 53. To run the DNS server on the master host, some configurations needs to be changed.

In /etc/dnsmasq.conf, add:

```
# Reverse DNS record for master
host-record=master.example.com, <master-IP>
# Wildcard DNS for OpenShift Applications - Points to Router
address=/apps.example.com/<master-IP>
# Forward .local queries to SkyDNS
server=/local/127.0.0.1#8053
# Forward reverse queries for service network to SkyDNS.
# This is for default OpenShift SDN - change as needed.
server=/17.30.172.in-addr.arpa/127.0.0.1#8053
```

With these settings, dnsmasq will pull from the /etc/hosts file on the master node.

Add the appropriate host names and IPs for all necessary hosts.

In master-config.yaml, change bindAddress to:

```
dnsConfig:
  bindAddress: 127.0.0.1:8053
```

When pods are created, they receive a copy of /etc/resolv.conf, which typically contains only the master DNS server so they can resolve external DNS requests. To enable internal DNS resolution, insert the dnsmasq server at the top of the server list. This way, dnsmasq will attempt to resolve requests internally first.

In /etc/resolv.conf all scheduled nodes:

```
nameserver 192.168.1.100 1
nameserver 192.168.1.1 2
```

- Add the internal DNS server.
- Pre-existing external DNS server.

Once the configurations are changed, restart the OpenShift Container Platform master and dnsmasq

services.

\$ systemctl restart atomic-openshift-master

\$ systemctl restart dnsmasq

22.10. BINDING PERSISTENT VOLUMES BY LABELS

22.10.1. Overview

This topic provides an end-to-end example for binding persistent volume claims (PVCs) to persistent volumes (PVs), by defining labels in the PV and matching selectors in the PVC. This feature is available for all storage options. It is assumed that a OpenShift Container Platform cluster contains persistent storage resources which are available for binding by PVCs.

A Note on Labels and Selectors

Labels are an OpenShift Container Platform feature that support user-defined tags (key-value pairs) as part of an object's specification. Their primary purpose is to enable the arbitrary grouping of objects by defining identical labels among them. These labels can then be targeted by selectors to match all objects with specified label values. It is this functionality we will take advantage of to enable our PVC to bind to our PV. For a more in-depth look at labels, see Pods and Services.

NOTE

For this example, we will be using modified GlusterFS PV and PVC specifications. However, implementation of selectors and labels is generic across for all storage options. See the relevant storage option for your volume provider to learn more about its unique configuration.

22.10.1.1. Assumptions

It is assumed that you have:

- An existing OpenShift Container Platform cluster with at least one master and one node
- At least one supported storage volume
- A user with **cluster-admin** privileges

22.10.2. Defining Specifications

NOTE

These specifications are tailored to **GlusterFS**. Consult the relevant storage option for your volume provider to learn more about its unique configuration.

22.10.2.1. Persistent Volume with Labels

Example 22.18. glusterfs-pv.yaml

apiVersion: v1

kind: PersistentVolume

metadata:

```
name: gluster-volume
labels: 1
    storage-tier: gold
    aws-availability-zone: us-east-1
spec:
    capacity:
        storage: 2Gi
    accessModes:
        - ReadWriteMany
    glusterfs:
        endpoints: glusterfs-cluster 2
        path: myVol1
        readOnly: false
    persistentVolumeReclaimPolicy: Retain
```

- Use labels to identify common attributes or characteristics shared among volumes. In this case, we defined the Gluster volume to have a custom attribute (key) named **storage-tier** with a value of **gold** assigned. A claim will be able to select a PV with **storage-tier=gold** to match this PV.
- Endpoints define the Gluster trusted pool and are discussed below.

22.10.2.2. Persistent Volume Claim with Selectors

A claim with a **selector** stanza (see example below) attempts to match existing, unclaimed, and non-prebound PVs. The existence of a PVC selector ignores a PV's capacity. However, **accessModes** are still considered in the matching criteria.

It is important to note that a claim must match **all** of the key-value pairs included in its **selector** stanza. If no PV matches the claim, then the PVC will remain unbound (Pending). A PV can subsequently be created and the claim will automatically check for a label match.

Example 22.19. glusterfs-pvc.yaml

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
   name: gluster-claim
spec:
   accessModes:
   - ReadWriteMany
   resources:
       requests:
       storage: 1Gi
   selector: 1
      matchLabels:
       storage-tier: gold
      aws-availability-zone: us-east-1
```

The **selector** stanza defines all labels necessary in a PV in order to match this claim.

22.10.2.3. Volume Endpoints

To attach the PV to the Gluster volume, endpoints should be configured before creating our objects.

Example 22.20. glusterfs-ep.yaml

```
apiVersion: v1
kind: Endpoints
metadata:
  name: glusterfs-cluster
subsets:
  - addresses:
    - ip: 192.168.122.221
  ports:
    - port: 1
  - addresses:
    - ip: 192.168.122.222
  ports:
    - port: 1
```

22.10.2.4. Deploy the PV, PVC, and Endpoints

For this example, run the **oc** commands as a **cluster-admin** privileged user. In a production environment, cluster clients might be expected to define and create the PVC.

```
# oc create -f glusterfs-ep.yaml
endpoints "glusterfs-cluster" created
# oc create -f glusterfs-pv.yaml
persistentvolume "gluster-volume" created
# oc create -f glusterfs-pvc.yaml
persistentvolumeclaim "gluster-claim" created
```

Lastly, confirm that the PV and PVC bound successfully.

```
# oc get pv,pvc
NAME
                  CAPACITY
                            ACCESSMODES
                                              STATUS
                                                         CLAIM
REASON
        AGE
gluster-volume
                  2Gi
                             RWX
                                              Bound
                                                         gfs-
trial/gluster-claim
                                7s
NAME
                  STATUS
                             VOLUME
                                              CAPACITY
                                                         ACCESSMODES
AGE
gluster-claim
                  Bound
                             gluster-volume
                                              2Gi
                                                         RWX
```

NOTE

PVCs are local to a project, whereas PVs are a cluster-wide, global resource. Developers and non-administrator users may not have access to see all (or any) of the available PVs.

22.11. USING STORAGE CLASSES FOR DYNAMIC PROVISIONING

22.11.1. Overview

In these examples we will walk through a few scenarios of various configuratons of StorageClasses and Dynamic Provisioning using Google Cloud Platform Compute Engine (GCE). These examples assume some familiarity with Kubernetes, GCE and Persistent Disks and OpenShift Container Platform is installed and properly configured to use GCE.

- Basic Dynamic Provisioning
- Defaulting Cluster Dynamic Provisioning Behavior

22.11.2. Scenario 1: Basic Dynamic Provisioning with Two Types of StorageClasses

StorageClasses can be used to differentiate and delineate storage levels and usages. In this case, the cluster-admin or storage-admin sets up two distinct classes of storage in GCE.

- slow: Cheap, efficient, and optimized for sequential data operations (slower reading and writing)
- fast: Optimized for higher rates of random IOPS and sustained throughput (faster reading and writing)

By creating these *StorageClasses*, the **cluster-admin** or **storage-admin** allows users to create claims requesting a particular level or service of *StorageClass*.

Example 22.21. StorageClass Slow Object Definitions

kind: StorageClass
apiVersion: storage.k8s.io/v1beta1
metadata:
 name: slow 1
provisioner: kubernetes.io/gce-pd 2
parameters:
 type: pd-standard 3
 zone: us-east1-d 4

- Name of the StorageClass.
- The provisioner plug-in to be used. This is a required field for *StorageClasses*.
- PD type. This example uses pd-standard, which has a slightly lower cost, rate of sustained IOPS, and throughput versus pd-ssd, which carries more sustained IOPS and throughput.
- The zone is required.

Example 22.22. StorageClass Fast Object Definition

kind: StorageClass
apiVersion: storage.k8s.io/v1beta1
metadata:
 name: fast
provisioner: kubernetes.io/gce-pd

```
parameters:
  type: pd-ssd
  zone: us-east1-d
```

As a cluster-admin or storage-admin, save both definitions as YAML files. For example, slow-gce.yaml and fast-gce.yaml. Then create the StorageClasses.

IMPORTANT

cluster-admin or **storage-admin** users are responsible for relaying the correct *StorageClass* name to the correct users, groups, and projects.

As a regular user, create a new project:

```
# oc new-project rh-eng
```

Create the claim YAML definition, save it to a file (pvc-fast.yaml):

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: pvc-engineering
  annotations:
    volume.beta.kubernetes.io/storage-class: fast
spec:
  accessModes:
    - ReadWriteMany
  resources:
    requests:
    storage: 10Gi
```

Add the claim with the oc create command:

```
# oc create -f pvc-fast.yaml
persistentvolumeclaim "pvc-engineering" created
```

Check to see if your claim is bound:

```
# oc get pvc
NAME STATUS VOLUME
```

CAPACITY ACCESSMODES AGE

pvc-engineering Bound pvc-e9b4fef7-8bf7-11e6-9962-42010af00004

10Gi RWX 2m

IMPORTANT

Since this claim was created and bound in the *rh-eng* project, it can be shared by any user in the same project.

As a **cluster-admin** or **storage-admin** user, view the recent dynamically provisioned Persistent Volume (PV).

oc get pv

NAME CAPACITY ACCESSMODES

RECLAIMPOLICY STATUS CLAIM REASON AGE

pvc-e9b4fef7-8bf7-11e6-9962-42010af00004 10Gi RWX

Delete Bound rh-eng/pvc-engineering 5m

IMPORTANT

Notice the RECLAIMPOLICY is *Delete* by default for all dynamically provisioned volumes. This means the volume only lasts as long as the claim still exists in the system. If you delete the claim, the volume is also deleted and all data on the volume is lost.

Finally, check the GCE console. The new disk has been created and is ready for use.

kubernetes-dynamic-pvc-e9b4fef7-8bf7-11e6-9962-42010af00004 SSD persistent disk 10 GB us-east1-d

Pods can now reference the persistent volume claim and start using the volume.

22.11.3. Scenario 2: How to enable Default StorageClass behavior for a Cluster

In this example, a **cluster-admin** or **storage-admin** enables a *default* storage class for all other users and projects that do not implicitly specify a *StorageClass* annotation in their claim. This is useful for a **cluster-admin** or **storage-admin** to provide easy management of a storage volume without having to set up or communicate specialized *StorageClasses* across the cluster.

This example builds upon Section 22.11.2, "Scenario 1: Basic Dynamic Provisioning with Two Types of StorageClasses". The cluster-admin or storage-admin will create another StorageClass for designation as the defaultStorageClass.

Example 22.23. Default StorageClass Object Definition

kind: StorageClass
apiVersion: storage.k8s.io/v1beta1
metadata:

name: generic 1
annotations:

storageclass.beta.kubernetes.io/is-default-class: "true" provisioner: kubernetes.io/gce-pd

449

parameters:

type: pd-standard zone: us-east1-d

- Name of the *StorageClass*, which needs to be unique in the cluster.
- 2 Annotation that marks this *StorageClass* as the default class. You must use "true" quoted in this version of the API. Without this annotation, OpenShift Container Platform considers this not the *default StorageClass*.

As a cluster-admin or storage-admin save the definition to a YAML file (generic-gce.yaml), then create the StorageClasses:

As a regular user, create a new claim definition without any *StorageClass* annotation and save it to a file (generic-pvc.yaml).

Example 22.24. default Storage Claim Object Definition

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: pvc-engineering2
spec:
  accessModes:
  - ReadWriteMany
  resources:
    requests:
    storage: 5Gi
```

Execute it and check the claim is bound:

```
# oc create -f generic-pvc.yaml
persistentvolumeclaim "pvc-engineering2" created
                                                                  3s
# oc get pvc
NAME
                   STATUS
                            VOLUME
CAPACITY ACCESSMODES
                        AGE
pvc-engineering
                   Bound
                            pvc-e9b4fef7-8bf7-11e6-9962-42010af00004
10Gi
          RWX
                         41m
pvc-engineering2
                   Bound
                            pvc-a9f70544-8bfd-11e6-9962-42010af00004
5Gi
          RWX
                         7s
```

pvc-engineering2 is bound to a dynamically provisioned Volume by default.

As a cluster-admin or storage-admin, view the Persistent Volumes defined so far:

```
# oc get pv
                                            CAPACITY
NAME
                                                       ACCESSMODES
RECLAIMPOLICY
                STATUS
                          CLAIM
                                                     REASON
                                                                AGE
pvc-a9f70544-8bfd-11e6-9962-42010af00004
                                            5Gi
                                                        RWX
                Bound
                          rh-eng/pvc-engineering2
                                                                5m
pvc-ba4612ce-8b4d-11e6-9962-42010af00004
                                            5Gi
                                                        RWO
                          mytest/gce-dyn-claim1
                                                                21h
                Bound
pvc-e9b4fef7-8bf7-11e6-9962-42010af00004
                                            10Gi
                                                        RWX
Delete
                Bound
                          rh-eng/pvc-engineering
                                                                46m 2
```

- This PV was bound to our default dynamic volume from the default StorageClass.
- This PV was bound to our first PVC from Section 22.11.2, "Scenario 1: Basic Dynamic Provisioning with Two Types of StorageClasses" with our fast StorageClass.

Create a manually provisioned disk using GCE (not dynamically provisioned). Then create a Persistent Volume that connects to the new GCE disk (pv-manual-gce.yaml).

Example 22.25. Manual PV Object Defition

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: pv-manual-gce
spec:
  capacity:
    storage: 35Gi
accessModes:
    - ReadWriteMany
gcePersistentDisk:
  readOnly: false
  pdName: the-newly-created-gce-PD
fsType: ext4
```

Execute the object definition file:

```
# oc create -f pv-manual-gce.yaml
```

Now view the PVs again. Notice that a pv-manual-gce volume is Available.

```
# oc get pv
                                                        ACCESSMODES
NAME
                                             CAPACITY
RECLAIMPOLICY
                STATUS
                             CLAIM
                                                         REASON
                                                                   AGE
pv-manual-qce
                                             35Gi
                                                         RWX
                Available
                                                                   4s
Retain
pvc-a9f70544-8bfd-11e6-9962-42010af00004
                                                         RWX
                                             5Gi
Delete
                Bound
                             rh-eng/pvc-engineering2
                                                                   12m
```

pvc-ba4612ce	-8b4d-11e6-99	62-42010af00004	5Gi	RWO	
Delete	Bound	mytest/gce-dyr	n-claim1		21h
pvc-e9b4fef7	-8bf7-11e6-99	62-42010af00004	10Gi	RWX	
Delete	Bound	rh-eng/pvc-eng	gineering		53m

Now create another claim identical to the **generic-pvc.yaml** PVC definition but change the name and do not set an annotation.

Example 22.26. Claim Object Definition

apiVersion: v1
kind: PersistentVolumeClaim
metadata:
 name: pvc-engineering3
spec:
 accessModes:
 - ReadWriteMany
resources:
 requests:
 storage: 15Gi

Because *default StorageClass* is enabled in this instance, the manually created PV does not satisfy the claim request. The user receives a new dynamically provisioned Persistent Volume.

```
# oc get pvc
NAME
                   STATUS
                             VOLUME
CAPACITY ACCESSMODES
                         AGE
pvc-engineering
                   Bound
                             pvc-e9b4fef7-8bf7-11e6-9962-42010af00004
10Gi
          RWX
                         1h
                   Bound
pvc-engineering2
                             pvc-a9f70544-8bfd-11e6-9962-42010af00004
          RWX
                         19m
5Gi
                             pvc-6fa8e73b-8c00-11e6-9962-42010af00004
pvc-engineering3
                   Bound
15Gi
           RWX
                         6s
```

IMPORTANT

Since the *default StorageClass* is enabled on this system, for the manually created Persistent Volume to get bound by the above claim and not have a new dynamic provisioned volume be bound, the PV would need to have been created in the *default StorageClass*.

Since the *default StorageClass* is enabled on this system, you would need to create the PV in the *default StorageClass* for the manually created Persistent Volume to get bound to the above claim and not have a new dynamic provisioned volume bound to the claim.

To fix this, the cluster-admin or storage-admin user simply needs to create another GCE disk or delete the first manual PV and use a PV object definition that assigns a *StorageClass* annotation (pv-manual-gce2.yaml) if necessary:

Example 22.27. Manual PV Spec with default StorageClass annotation

apiVersion: v1

```
kind: PersistentVolume
metadata:
name: pv-manual-gce2
annotations:
   volume.beta.kubernetes.io/storage-class: generic 1
spec:
   capacity:
    storage: 35Gi
accessModes:
    - ReadWriteMany
gcePersistentDisk:
   readOnly: false
   pdName: the-newly-created-gce-PD
   fsType: ext4
```

The annotation for previously created generic StorageClass.

Execute the object definition file:

```
# oc create -f pv-manual-gce2.yaml
```

List the PVs:

# oc get pv			CADACTTV	ACCECCMOD	FC
NAME RECLAIMPOLICY	STATUS	CLATM	CAPACITY	ACCESSMOD REASON	AGE
pv-manual-gce	0171100	OL/(III	35Gi	RWX	NOL
Retain	Available				4s 1
pv-manual-gce2			35Gi	RWX	_
Retain	Bound	rh-eng/pvc-eng	ineering3		4s 2
pvc-a9f70544-8b	fd-11e6-9962	-42010af00004	5Gi	RWX	
Delete	Bound	rh-eng/pvc-eng	ineering2		12m
pvc-ba4612ce-8b	4d-11e6-9962	-42010af00004	5Gi	RWO	
Delete	Bound	mytest/gce-dyn	-claim1		21h
pvc-e9b4fef7-8b	f7-11e6-9962	-42010af00004	10Gi	RWX	
Delete	Bound	rh-eng/pvc-eng	ineering		53m

- The original manual PV, still unbound and Available. This is because it was not created in the default StorageClass.
- The second PVC (other than the name) is bound to the Available manually created PV pv-manual-gce2.

IMPORTANT

Notice that all dynamically provisioned volumes by default have a *RECLAIMPOLICY* of *Delete*. Once the PVC dynamically bound to the PV is deleted, the GCE volume is deleted and all data is lost. However, the manually created PV has a default *RECLAIMPOLICY* of *Retain*.

22.12. USING STORAGE CLASSES FOR EXISTING LEGACY STORAGE

22.12.1. Overview

In this example, a legacy data volume exists and a **cluster-admin** or **storage-admin** needs to make it available for consumption in a particular project. Using *StorageClasses* decreases the likelihood of other users and projects gaining access to this volume from a claim because the claim would have to have an exact matching value for the *StorageClass* annotation. This example also disables dynamic provisioning. This example assumes:

- Some familiarity with OpenShift Container Platform, GCE, and Persistent Disks
- OpenShift Container Platform is properly configured to use GCE.

22.12.1.1. Scenario 1: Link StorageClass to existing Persistent Volume with Legacy Data

As a **cluster-admin** or **storage-admin**, define and create the *StorageClass* for historical financial data.

Example 22.28. StorageClass finance-history Object Definitions

kind: StorageClass

apiVersion: storage.k8s.io/v1beta1

metadata:

name: finance-history 1

provisioner: no-provisioning 2

parameters: 3

- Name of the StorageClass.
- This is a required field, but since there is to be no dynamic provisioning, a value must be put here as long as it is not an actual provisioner plug-in type.
- Parameters can simply be left blank, since these are only used for the dynamic provisioner.

Save the definitions to a YAML file (finance-history-storageclass.yaml) and create the StorageClass.

```
# oc create -f finance-history-storageclass.yaml
storageclass "finance-history" created
```

IMPORTANT

cluster-admin or **storage-admin** users are responsible for relaying the correct *StorageClass* name to the correct users, groups, and projects.

The StorageClass exists. A cluster-admin or storage-admin can create the Persistent Volume (PV) for use with the StorageClass. Create a manually provisioned disk using GCE (not dynamically provisioned) and a Persistent Volume that connects to the new GCE disk (gce-pv.yaml).

Example 22.29. Finance History PV Object

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: pv-finance-history
  annotations:
    volume.beta.kubernetes.io/storage-class: finance-history 1
spec:
    capacity:
        storage: 35Gi
    accessModes:
        - ReadWriteMany
    gcePersistentDisk:
        readOnly: false
        pdName: the-existing-PD-volume-name-that-contains-the-valuable-data
2
    fsType: ext4
```

- The StorageClass annotation, that must match exactly.
- The name of the GCE disk that already exists and contains the legacy data.

As a cluster-admin or storage-admin, create and view the PV.

```
# oc create -f gce-pv.yaml
persistentvolume "pv-finance-history" created
# oc get pv
NAME
                   CAPACITY
                              ACCESSMODES
                                            RECLAIMPOLICY
                                                           STATUS
                            REASON
CLAIM
                                     AGE
pv-finance-history
                    35Gi
                               RWX
                                             Retain
                                                            Available
2d
```

Notice you have a pv-finance-history Available and ready for consumption.

As a user, create a Persistent Volume Claim (PVC) as a YAML file and specify the correct *StorageClass* annotation:

Example 22.30. Claim for finance-history Object Definition

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: pvc-finance-history
  annotations:
    volume.beta.kubernetes.io/storage-class: finance-history
spec:
```

accessModes:

- ReadWriteMany

resources: requests:

storage: 20Gi

The *StorageClass* annotation, that must match exactly or the claim will go unbound until it is deleted or another *StorageClass* is created that matches the annotation.

Create and view the PVC and PV to see if it is bound.

```
# oc create -f pvc-finance-history.yaml
persistentvolumeclaim "pvc-finance-history" created
# oc get pvc
NAME
                      STATUS
                               VOLUME
                                                     CAPACITY
ACCESSMODES
             AGE
                               pv-finance-history
                                                                RWX
pvc-finance-history
                      Bound
                                                    35Gi
9m
# oc get pv (cluster/storage-admin)
                    CAPACITY
NAME
                               ACCESSMODES
                                              RECLAIMPOLICY
                                                              STATUS
CLAIM
                             REASON
                                       AGE
pv-finance-history
                                              Retain
                                                              Bound
                    35Gi
                               RWX
default/pvc-finance-history
                                        5m
```

IMPORTANT

You can use *StorageClasses* in the same cluster for both legacy data (no dynamic provisioning) and with dynamic provisioning.

22.13. CONFIGURING AZURE BLOB STORAGE FOR INTEGRATED DOCKER REGISTRY

22.13.1. Overview

This topic reviews how to configure Azure Blob Storage for OpenShift integrated Docker registry.

22.13.2. Before You Begin

- Create a storage container using Microsoft Azure Portal, Microsoft Azure CLI, or Microsoft Azure Storage Explorer. Keep a note of the storage account name, storage account key and container name.
- Deploy the integrated Docker registry if it is not deployed.

22.13.3. Overriding Registry Configuration

To create a new registry pod and replace the old pod automatically:

1. Create a new registry configuration file called *registryconfig.yaml* and add the following information:

```
version: 0.1
log:
  level: debug
http:
  addr: :5000
storage:
  cache:
    blobdescriptor: inmemory
  delete:
    enabled: true
  azure: 1
    accountname: azureblobacc
    accountkey: azureblobacckey
    container: azureblobname
auth:
  openshift:
    realm: openshift
middleware:
  registry:
    - name: openshift
  repository:
    - name: openshift
      options:
        acceptschema2: false
        pullthrough: true
        enforcequota: false
        projectcachettl: 1m
        blobrepositorycachettl: 10m
  storage:
    - name: openshift
```

- Replace the values for accountname, acountkey, and container with storage account name, storage account key, and storage container name respectively.
- 2. Create a new registry configuration:

```
$ oc secrets new registry-config config.yaml=registryconfig.yaml
```

3. Add the secret:

```
$ oc volume dc/docker-registry --add --type=secret \
    --secret-name=registry-config -m /etc/docker/registry/
```

4. Set the REGISTRY_CONFIGURATION_PATH environment variable:

```
$ oc set env dc/docker-registry \
    REGISTRY_CONFIGURATION_PATH=/etc/docker/registry/config.yaml
```

- 5. If you already created a registry configuration:
 - a. Delete the secret:

\$ oc delete secret registry-config

b. Create a new registry configuration:

\$ oc secrets new registry-config config.yaml=registryconfig.yaml

c. Update the configuration by starting a new rollout:

\$ oc rollout latest docker-registry

CHAPTER 23. WORKING WITH HTTP PROXIES

23.1. OVERVIEW

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. Configuring OpenShift Container Platform to use these proxies can be as simple as setting standard environment variables in configuration or JSON files. This can be done during an advanced installation or configured after installation.

The proxy configuration must be the same on each host in the cluster. Therefore, when setting up the proxy or modifying it, you must update the files on each OpenShift Container Platform host to the same values. Then, you must restart OpenShift Container Platform services on each host in the cluster.

The NO_PROXY, HTTP_PROXY, and HTTPS_PROXY environment variables are found in each host's /etc/sysconfig/atomic-openshift-master file (for single master configuration), /etc/sysconfig/atomic-openshift-master-controllers files (for multi-master configuration) and /etc/sysconfig/atomic-openshift-node.

23.2. CONFIGURING NO PROXY

The NO_PROXY environment variable lists all of the OpenShift Container Platform components and all IP addresses that are managed by OpenShift Container Platform.

On the OpenShift service accepting the CIDR, **NO_PROXY** accepts a comma-separated list of hosts, IP addresses, or IP ranges in CIDR format:

For master hosts

- Node host name
- Master IP or host name
- IP address of etcd hosts

For node hosts

• Master IP or host name

For the Docker service

- Registry service IP and host name
- Registry service URL docker-registry.default.svc.cluster.local
- Registry route host name (if created)

NOTE

When using Docker, Docker accepts a comma-separated list of hosts, domain extensions, or IP addresses, but does not accept IP ranges in CIDR format, which are only accepted by OpenShift services. The `no_proxy' variable should contain a comma-separated list of domain extensions that the proxy should *not* be used for.

For example, if no_proxy is set to .school.edu, the proxy will not be used to retrieve documents from the specific school.

NO_PROXY also includes the SDN network and service IP addresses as found in the *master-config.yaml* file.

/etc/origin/master/master-config.yaml

```
networkConfig:
```

clusterNetworkCIDR: 10.1.0.0/16
serviceNetworkCIDR: 172.30.0.0/16

OpenShift Container Platform does not accept * as a wildcard attached to a domain suffix. For example, the following would be accepted:

```
NO_PROXY=.example.com
```

However, the following would not be:

```
NO_PROXY=*.example.com
```

The only wildcard NO_PROXY accepts is a single * character, which matches all hosts, and effectively disables the proxy.

Each name in this list is matched as either a domain which contains the host name as a suffix, or the host name itself.

For instance, example.com would match example.com, example.com:80, and www.example.com.

23.3. CONFIGURING HOSTS FOR PROXIES

1. Edit the proxy environment variables in the OpenShift Container Platform control files. Ensure all of the files in the cluster are correct.

```
HTTP_PROXY=http://<user>:<password>@<ip_addr>:<port>/
HTTPS_PROXY=https://<user>:<password>@<ip_addr>:<port>/
NO_PROXY=master.hostname.example.com, 10.1.0.0/16, 172.30.0.0/16
```

- Supports host names and CIDRs. Must include the SDN network and service IP ranges 10.1.0.0/16,172.30.0.0/16 by default.
- 2. Restart the master or node host as appropriate:

```
# systemctl restart atomic-openshift-master
# systemctl restart atomic-openshift-node
```

For multi-master installations:

```
# systemctl restart atomic-openshift-master-controllers
# systemctl restart atomic-openshift-master-api
```

23.4. CONFIGURING HOSTS FOR PROXIES USING ANSIBLE

During advanced installations, the NO_PROXY, HTTP_PROXY, and HTTPS_PROXY environment variables can be configured using the openshift_no_proxy, openshift_http_proxy, and openshift_https_proxy parameters, which are configurable in the inventory file.

Example 23.1. Example Proxy Configuration with Ansible

```
# Global Proxy Configuration
# These options configure HTTP_PROXY, HTTPS_PROXY, and NOPROXY
environment
# variables for docker and master services.
openshift_http_proxy=http://<user>:<password>@<ip_addr>:<port>
openshift_https_proxy=https://<user>:<password>@<ip_addr>:<port>
openshift_no_proxy='.hosts.example.com, some-host.com'
#
# Most environments do not require a proxy between OpenShift masters, nodes, and
# etcd hosts. So automatically add those host names to the openshift_no_proxy list.
# If all of your hosts share a common domain you may wish to disable this and
# specify that domain above.
# openshift_generate_no_proxy_hosts=True
```

NOTE

There are additional proxy settings that can be configured for builds using Ansible parameters. For example:

The openshift_builddefaults_git_http_proxy and openshift_builddefaults_git_https_proxy parameters allow you to use a proxy for Git cloning

The openshift_builddefaults_http_proxy and openshift_builddefaults_https_proxy parameters can make environment variables available to the Docker build strategy and Custom build strategy processes.

23.5. PROXYING DOCKER PULL

OpenShift Container Platform node hosts need to perform push and pull operations to Docker registries. If you have a registry that does not need a proxy for nodes to access, include the **NO_PROXY** parameter with:

- the registry's host name,
- the registry service's IP address, and

• the service name.

This blacklists that registry, leaving the external HTTP proxy as the only option.

1. Retrieve the registry service's IP address docker_registy_ip by running:

```
$ oc describe svc/docker-registry -n default

Name: docker-registry

Namespace: default

Labels: docker-registry=default

Selector: docker-registry=default

Type: ClusterIP

IP: 172.30.163.183 1

Port: 5000-tcp 5000/TCP

Endpoints: 10.1.0.40:5000
```

No events.

Registry service IP.

Session Affinity: ClientIP

2. Edit the /etc/sysconfig/docker file and add the NO_PROXY variables in shell format, replacing <docker_registry_ip> with the IP address from the previous step.

```
HTTP_PROXY=http://<user>:<password>@<ip_addr>:<port>/
HTTPS_PROXY=https://<user>:<password>@<ip_addr>:<port>/
NO_PROXY=master.hostname.example.com,<docker_registry_ip>,docker-registry_default.svc.cluster.local
```

3. Restart the Docker service:

systemctl restart docker

23.6. USING MAVEN BEHIND A PROXY

Using Maven with proxies requires using the HTTP_PROXY_NONPROXYHOSTS variable.

See the Red Hat JBoss Enterprise Application Platform for OpenShift documentation for information about configuring your OpenShift Container Platform environment for Red Hat JBoss Enterprise Application Platform, including the step for setting up Maven behind a proxy.

23.7. CONFIGURING S2I BUILDS FOR PROXIES

S2I builds fetch dependencies from various locations. You can use a .s2i/environment file to specify simple shell variables and OpenShift Container Platform will react accordingly when seeing build images.

The following are the supported proxy environment variables with example values:

```
HTTP_PROXY=http://USERNAME:PASSWORD@10.0.1.1:8080/
HTTPS_PROXY=https://USERNAME:PASSWORD@10.0.0.1:8080/
NO_PROXY=master.hostname.example.com
```

23.8. CONFIGURING DEFAULT TEMPLATES FOR PROXIES

The example templates available in OpenShift Container Platform by default do not include settings for HTTP proxies. For existing applications based on these templates, modify the source section of the application's build configuration and add proxy settings:

```
source:
  type: Git
  git:
    uri: https://github.com/openshift/ruby-hello-world
    httpProxy: http://proxy.example.com
    httpsProxy: https://proxy.example.com
    noProxy: somedomain.com, otherdomain.com
```

This is similar to the process for using proxies for Git cloning.

23.9. SETTING PROXY ENVIRONMENT VARIABLES IN PODS

You can set the NO_PROXY, HTTP_PROXY, and HTTPS_PROXY environment variables in the templates.spec.containers stanza in a deployment configuration to pass proxy connection information. The same can be done for configuring a Pod's proxy at runtime:

```
...
containers:
- env:
- name: "HTTP_PROXY"
   value: "http://<user>:<password>@<ip_addr>:<port>"
...
```

You can also use the **oc set env** command to update an existing deployment configuration with a new environment variable:

```
$ oc set env dc/frontend HTTP_PROXY=http://<user>:<password>@<ip_addr>:
<port>
```

If you have a ConfigChange trigger set up in your OpenShift Container Platform instance, the changes happen automatically. Otherwise, manually redeploy your application for the changes to take effect.

23.10. GIT REPOSITORY ACCESS

If your Git repository can only be accessed using a proxy, you can define the proxy to use in the **source** section of the **BuildConfig**. You can configure both a HTTP and HTTPS proxy to use. Both fields are optional. Domains for which no proxying should be performed can also be specified via the **NoProxy** field.

NOTE

Your source URI must use the HTTP or HTTPS protocol for this to work.

source:

git:

uri: "https://github.com/openshift/ruby-hello-world"

httpProxy: http://proxy.example.com httpsProxy: https://proxy.example.com noProxy: somedomain.com, otherdomain.com

CHAPTER 24. CONFIGURING GLOBAL BUILD DEFAULTS AND OVERRIDES

24.1. OVERVIEW

Developers can define settings in specific build configurations within their projects, such as configuring a proxy for Git cloning. Rather than requiring developers to define certain settings in each of their build configurations, cluster administrators can use admission control plug-ins to configure global build defaults and overrides that automatically use these settings in any build.

The settings from these plug-ins are not set in the build configurations or builds themselves, but rather are only used during the build process. This allows administrators to change the global configuration at any time, and any builds that are re-run from existing build configurations or builds will get the new settings.

The **BuildDefaults** admission control plug-in allows administrators to set global defaults for settings such as the Git HTTP and HTTPS proxy, as well as default environment variables. These defaults do not overwrite values that have been configured for a specific build. However, if those values are not present on the build definition, they are set to the default value.

The **BuildOverrides** admission control plug-in allows administrators to override a setting in a build, regardless of the value stored in the build. It currently supports overriding the **forcePull** flag on a build strategy to enforce always refreshing the local image during a build by pulling the image from the registry. This ensures that a user can only build with an image that they are allowed to pull.

24.2. SETTING GLOBAL BUILD DEFAULTS

You can set global build defaults two ways:

- using Ansible and the advanced installation tool
- manually by modifying the *master-config.yaml* file

24.2.1. Configuring Global Build Defaults with Ansible

During advanced installations, the **BuildDefaults** plug-in can be configured using the following parameters, which are configurable in the inventory file:

- openshift_builddefaults_http_proxy
- openshift_builddefaults_https_proxy
- openshift_builddefaults_no_proxy
- openshift_builddefaults_git_http_proxy
- openshift_builddefaults_git_https_proxy
- openshift_builddefaults_git_no_proxy
- openshift_builddefaults_image_labels
- openshift_builddefaults_nodeselectors

- openshift_builddefaults_annotations
- openshift_builddefaults_resources_requests_cpu
- openshift_builddefaults_resources_requests_memory
- openshift_builddefaults_resources_limits_cpu
- openshift_builddefaults_resources_limits_memory

Example 24.1. Example Build Defaults Configuration with Ansible

```
# These options configure the BuildDefaults admission controller which
injects
# configuration into Builds. Proxy related values will default to the
global proxy
# config values. You only need to set these if they differ from the
global proxy settings.
openshift_builddefaults_http_proxy=http://USER:PASSWORD@HOST:PORT
openshift_builddefaults_https_proxy=https://USER:PASSWORD@HOST:PORT
openshift_builddefaults_no_proxy=mycorp.com
openshift_builddefaults_git_http_proxy=http://USER:PASSWORD@HOST:PORT
openshift_builddefaults_git_https_proxy=https://USER:PASSWORD@HOST:PORT
openshift_builddefaults_git_no_proxy=mycorp.com
openshift_builddefaults_image_labels=
[{'name':'imagelabelname1','value':'imagelabelvalue1'}]
openshift_builddefaults_nodeselectors={'nodelabel1':'nodelabelvalue1'}
openshift_builddefaults_annotations=
{ 'annotationkey1': 'annotationvalue1' }
openshift_builddefaults_resources_requests_cpu=100m
openshift_builddefaults_resources_requests_memory=256m
openshift_builddefaults_resources_limits_cpu=1000m
openshift_builddefaults_resources_limits_memory=512m
# Or you may optionally define your own build defaults configuration
serialized as json
#openshift_builddefaults_json='{"BuildDefaults":{"configuration":
{"apiVersion":"v1","env":
[{"name":"HTTP_PROXY","value":"http://proxy.example.com.redhat.com:3128"
}, {"name":"NO_PROXY", "value":"ose3-
master.example.com"}], "gitHTTPProxy": "http://proxy.example.com:3128", "gi
tNoProxy": "ose3-master.example.com", "kind": "BuildDefaultsConfig"}}}'
```

24.2.2. Manually Setting Global Build Defaults

To configure the **BuildDefaults** plug-in:

1. Add a configuration for it in the /etc/origin/master/master-config.yaml file on the master nodes:

```
admissionConfig:
pluginConfig:
BuildDefaults:
configuration:
```

```
apiVersion: v1
kind: BuildDefaultsConfig
gitHTTPProxy: http://my.proxy:8080 1
gitHTTPSProxy: https://my.proxy:8443 2
qitNoProxy: somedomain.com, otherdomain.com 3
env:
- name: HTTP_PROXY 4
  value: http://my.proxy:8080
- name: HTTPS PROXY 5
 value: https://my.proxy:8443
- name: BUILD_LOGLEVEL 6
 value: 4
- name: CUSTOM_VAR 7
  value: custom_value
imageLabels:
- name: url 8
  value: https://containers.example.org
- name: vendor
  value: ExampleCorp Ltd.
nodeSelector: 9
  key1: value1
  key2: value2
annotations: 10
  key1: value1
  key2: value2
resources: 111
  requests:
    cpu: "100m"
    memory: "256Mi"
  limits:
    cpu: "100m"
    memory: "256Mi"
```

- Sets the HTTP proxy to use when cloning source code from a Git repository.
- 2 Sets the HTTPS proxy to use when cloning source code from a Git repository.
- 3 Sets the list of domains for which proxying should not be performed.
- Default environment variable that sets the HTTP proxy to use during the build. This can be used for downloading dependencies during the assemble and build phases.
- Default environment variable that sets the HTTPS proxy to use during the build. This can be used for downloading dependencies during the assemble and build phases.
- Default environment variable that sets the build log level during the build.
- Additional default environment variable that will be added to every build.
- 8 Labels to be applied to every image built. Users can override these in their **BuildConfig**.
- 9 Build pods will only run on nodes with the key1=value2 and key2=value2 labels. Users can define a different set of nodeSelectors for their builds in which case these values will be ignored.

- Build pods will have these annotations added to them.
- Sets the default resources to the build pod if the **BuildConfig** does not have related resource defined.
- 2. Restart the master service for the changes to take effect:

systemctl restart atomic-openshift-master

24.3. SETTING GLOBAL BUILD OVERRIDES

You can set global build overrides two ways:

- using Ansible and the advanced installation tool
- manually by modifying the *master-config.yaml* file

24.3.1. Configuring Global Build Overrides with Ansible

During advanced installations, the **BuildOverrides** plug-in can be configured using the following parameters, which are configurable in the inventory file:

- openshift_buildoverrides_force_pull
- openshift_buildoverrides_image_labels
- openshift_buildoverrides_nodeselectors
- openshift_buildoverrides_annotations

Example 24.2. Example Build Overrides Configuration with Ansible

```
# These options configure the BuildOverrides admission controller which
injects
# configuration into Builds.
openshift_buildoverrides_force_pull=true
openshift_buildoverrides_image_labels=
[{'name':'imagelabelname1', 'value':'imagelabelvalue1'}]
openshift_buildoverrides_nodeselectors={'nodelabel1':'nodelabelvalue1'}
openshift_buildoverrides_annotations=
{'annotationkey1':'annotationvalue1'}

# Or you may optionally define your own build overrides configuration
serialized as json
#openshift_buildoverrides_json='{"BuildOverrides":{"configuration":
{"apiVersion":"v1", "kind":"BuildDefaultsConfig", "forcePull":"true"}}}'
```

24.3.2. Manually Setting Global Build Overrides

To configure the BuildOverrides plug-in:

1. Add a configuration for it in the /etc/origin/master/master-config.yaml file on masters:

```
admissionConfig:
  pluginConfig:
    BuildOverrides:
     configuration:
        apiVersion: v1
        kind: BuildOverridesConfig
        forcePull: true 1
        imageLabels:
        - name: distribution-scope 2
          value: private
        nodeSelector: 3
          key1: value1
          key2: value2
        annotations: 4
          key1: value1
          key2: value2
```

- Force all builds to pull their builder image and any source images before starting the build.
- Additional labels to be applied to every image built. Labels defined here take precedence over labels defined in **BuildConfig**.
- Build pods will only run on nodes with the key1=value2 and key2=value2 labels. Users can define additional key/value labels to further constrain the set of nodes a build runs on, but the node must have at least these labels.
- 4 Build pods will have these annotations added to them.
- 2. Restart the master service for the changes to take effect:

```
# systemctl restart atomic-openshift-master
```

CHAPTER 25. CONFIGURING PIPELINE EXECUTION

25.1. OVERVIEW

The first time a user creates a build configuration using the Pipeline build strategy, OpenShift Container Platform looks for a template named jenkins-ephemeral in the openshift namespace and instantiates it within the user's project. The jenkins-ephemeral template that ships with OpenShift Container Platform creates, upon instantiation:

- a deployment configuration for Jenkins using the official OpenShift Container Platform Jenkins image
- a service and route for accessing the Jenkins deployment
- a new Jenkins service account
- rolebindings to grant the service account edit access to the project

Cluster administrators can control what is created by either modifying the content of the built-in template, or by editing the cluster configuration to direct the cluster to a different template location.

To modify the content of the default template:

```
$ oc edit template jenkins-ephemeral -n openshift
```

To use a different template, such as the jenkins-persistent template which uses persistent storage for Jenkins, add the following to your master configuration file:

```
jenkinsPipelineConfig:
  autoProvisionEnabled: true 1
  templateNamespace: openshift 2
  templateName: jenkins-pipeline 3
  serviceName: jenkins-pipeline-svc 4
  parameters: 5
   key1: value1
  key2: value2
```

- Defaults to true if unspecified. If false, then no template will be instantiated.
- 2 Namespace containing the template to be instantiated.
- Name of the template to be instantiated.
- Name of the service to be created by the template upon instantiation.
- 6 Optional values to pass to the template during instantiation.

When a Pipeline build configuration is created, OpenShift Container Platform looks for a Service matching serviceName. This means serviceName must be chosen such that it is unique in the project. If no Service is found, OpenShift Container Platform instantiates the jenkinsPipelineConfig template. If this is not desirable (if you would like to use a Jenkins server external to OpenShift Container Platform, for example), there are a few things you can do, depending on who you are.

- If you are a cluster administrator, simply set **autoProvisionEnabled** to **false**. This will disable autoprovisioning across the cluster.
- If you are an unpriviledged user, a Service must be created for OpenShift Container Platform
 to use. The service name must match the cluster configuration value of serviceName in the
 jenkinsPipelineConfig. The default value is jenkins. If you are disabling
 autoprovisioning because you are running a Jenkins server outside your project, it is
 recommended that you point this new service to your existing Jenkins server. See: Integrating
 External Services

The latter option could also be used to disable autoprovisioning in select projects only.

CHAPTER 26. CONFIGURING ROUTE TIMEOUTS

After installing OpenShift Container Platform and deploying a router, you can configure the default timeouts for an existing route when you have services in need of a low timeout, as required for Service Level Availability (SLA) purposes, or a high timeout, for cases with a slow back end.

Using the oc annotate command, add the timeout to the route:

For example, to set a route named myroute to a timeout of two seconds:

```
# oc annotate route myroute --overwrite
haproxy.router.opensfhit.io/timeout=2s
```

Supported time units are microseconds (us), milliseconds (ms), seconds (s), minutes (m), hours (h), or days (d).

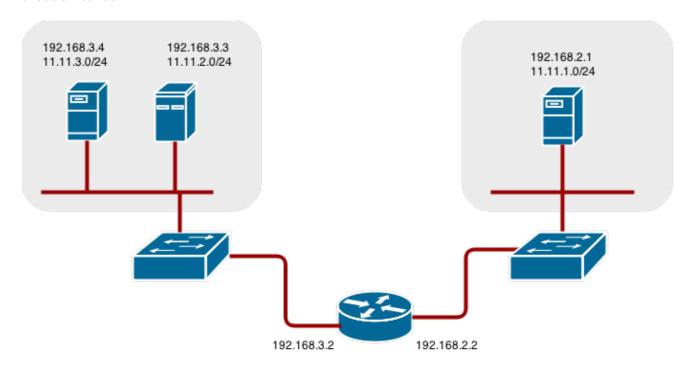

CHAPTER 27. CONFIGURING NATIVE CONTAINER ROUTING

27.1. NETWORK OVERVIEW

The following describes a general network setup:

- 11.11.0.0/16 is the container network.
- The 11.11.x.0/24 subnet is reserved for each node and assigned to the Docker Linux bridge.
- Each node has a route to the router for reaching anything in the 11.11.0.0/16 range, except the local subnet.
- The router has routes for each node, so it can be directed to the right node.
- Existing nodes do not need any changes when new nodes are added, unless the network topology is modified.
- IP forwarding is enabled on each node.

The following diagram shows the container networking setup described in this topic. It uses one Linux node with two network interface cards serving as a router, two switches, and three nodes connected to these switches.

27.2. CONFIGURE NATIVE CONTAINER ROUTING

You can set up container networking using existing switches and routers, and the kernel networking stack in Linux.

As a network administrator, you must modify, or create a script to modify, the router or routers when new nodes are added to the cluster.

You can adapt this process to use with any type of router.

27.3. SETTING UP A NODE FOR CONTAINER NETWORKING

1. Assign an unused 11.11.x.0/24 subnet IP address to the Linux bridge on the node:

```
# brctl addbr lbr0
# ip addr add 11.11.1.1/24 dev lbr0
# ip link set dev lbr0 up
```

2. Modify the Docker startup script to use the new bridge. By default, the startup script is the /etc/sysconfig/docker file:

```
# docker -d -b lbr0 --other-options
```

3. Add a route to the router for the 11.11.0.0/16 network:

```
# ip route add 11.11.0.0/16 via 192.168.2.2 dev p3p1
```

4. Enable IP forwarding on the node:

```
# sysctl -w net.ipv4.ip_forward=1
```

27.4. SETTING UP A ROUTER FOR CONTAINER NETWORKING

The following procedure assumes a Linux box with multiple NICs is used as a router. Modify the steps as required to use the syntax for a particular router:

1. Enable IP forwarding on the router:

```
# sysctl -w net.ipv4.ip_forward=1
```

2. Add a route for each node added to the cluster:

```
# ip route add <node_subnet> via <node_ip_address> dev <interface
through which node is L2 accessible>
# ip route add 11.11.1.0/24 via 192.168.2.1 dev p3p1
# ip route add 11.11.2.0/24 via 192.168.3.3 dev p3p2
# ip route add 11.11.3.0/24 via 192.168.3.4 dev p3p2
```

CHAPTER 28. ROUTING FROM EDGE LOAD BALANCERS

28.1. OVERVIEW

Pods inside of an OpenShift Container Platform cluster are only reachable via their IP addresses on the cluster network. An edge load balancer can be used to accept traffic from outside networks and proxy the traffic to pods inside the OpenShift Container Platform cluster. In cases where the load balancer is not part of the cluster network, routing becomes a hurdle as the internal cluster network is not accessible to the edge load balancer.

To solve this problem where the OpenShift Container Platform cluster is using OpenShift SDN as the cluster networking solution, there are two ways to achieve network access to the pods.

28.2. INCLUDING THE LOAD BALANCER IN THE SDN

If possible, run an OpenShift Container Platform node instance on the load balancer itself that uses OpenShift SDN as the networking plug-in. This way, the edge machine gets its own Open vSwitch bridge that the SDN automatically configures to provide access to the pods and nodes that reside in the cluster. The *routing table* is dynamically configured by the SDN as pods are created and deleted, and thus the routing software is able to reach the pods.

Mark the load balancer machine as an unschedulable node so that no pods end up on the load balancer itself:

```
$ oadm manage-node <load_balancer_hostname> --schedulable=false
```

If the load balancer comes packaged as a container, then it is even easier to integrate with OpenShift Container Platform: Simply run the load balancer as a pod with the host port exposed. The prepackaged HAProxy router in OpenShift Container Platform runs in precisely this fashion.

28.3. ESTABLISHING A TUNNEL USING A RAMP NODE

In some cases, the previous solution is not possible. For example, an **F5 BIG-IP®** host cannot run an OpenShift Container Platform node instance or the OpenShift Container Platform SDN because **F5®** uses a custom, incompatible Linux kernel and distribution.

Instead, to enable F5 BIG-IP® to reach pods, you can choose an existing node within the cluster network as a *ramp node* and establish a tunnel between the F5 BIG-IP® host and the designated ramp node. Because it is otherwise an ordinary OpenShift Container Platform node, the ramp node has the necessary configuration to route traffic to any pod on any node in the cluster network. The ramp node thus assumes the role of a gateway through which the F5 BIG-IP® host has access to the entire cluster network.

Following is an example of establishing an **ipip** tunnel between an **F5 BIG-IP®** host and a designated ramp node.

On the F5 BIG-IP® host:

1. Set the following variables:

```
# F5_IP=10.3.89.66 1
# RAMP_IP=10.3.89.89 2
# TUNNEL_IP1=10.3.91.216 3
```

- # CLUSTER_NETWORK=10.128.0.0/14 4
- The F5_IP and RAMP_IP variables refer to the F5 BIG-IP® host's and the ramp node's IP addresses, respectively, on a shared, internal network.
- An arbitrary, non-conflicting IP address for the F5® host's end of the ipip tunnel.
- The overlay network CIDR that the OpenShift SDN uses to assign addresses to pods.
- 2. Delete any old route, self, tunnel and SNAT pool:

```
# tmsh delete net route $CLUSTER_NETWORK || true
# tmsh delete net self SDN || true
# tmsh delete net tunnels tunnel SDN || true
# tmsh delete ltm snatpool SDN_snatpool || true
```

3. Create the new tunnel, self, route and SNAT pool and use the SNAT pool in the virtual servers:

```
# tmsh create net tunnels tunnel SDN \
    \{ description "OpenShift SDN" local-address \
    $F5_IP profile ipip remote-address $RAMP_IP \}
# tmsh create net self SDN \{ address \
        ${TUNNEL_IP1}/24 allow-service all vlan SDN \}
# tmsh create net route $CLUSTER_NETWORK interface SDN
# tmsh create ltm snatpool SDN_snatpool members add { $TUNNEL_IP1 }
# tmsh modify ltm virtual ose-vserver source-address-translation {
    type snat pool SDN_snatpool }
# tmsh modify ltm virtual https-ose-vserver source-address-
    translation { type snat pool SDN_snatpool }
```

On the ramp node:

1. Set the following variables:

- A second, arbitrary IP address for the ramp node's end of the **ipip** tunnel.
- The overlay network CIDR that the OpenShift SDN uses to assign addresses to pods.
- 2. Delete any old tunnel:

```
# ip tunnel del tun1 || true
```

3. Create the ipip tunnel on the ramp node, using a suitable L2-connected interface (e.g., eth0):

```
# ip tunnel add tun1 mode ipip \
    remote $F5_IP dev eth0
# ip addr add $TUNNEL_IP2 dev tun1
# ip link set tun1 up
```

```
# ip route add $TUNNEL_IP1 dev tun1
# ping -c 5 $TUNNEL_IP1
```

4. SNAT the tunnel IP with an unused IP from the SDN subnet:

```
# source /run/openshift-sdn/config.env
# tap1=$(ip -o -4 addr list tun0 | awk '{print $4}' | cut -d/ -f1 |
head -n 1)
# subaddr=$(echo ${OPENSHIFT_SDN_TAP1_ADDR:-"$tap1"} | cut -d "." -f
1,2,3)
# export RAMP_SDN_IP=${subaddr}.254
```

5. Assign this RAMP_SDN_IP as an additional address to tun0 (the local SDN's gateway):

```
# ip addr add ${RAMP_SDN_IP} dev tun0
```

6. Modify the OVS rules for SNAT:

```
# ipflowopts="cookie=0x999,ip"
# arpflowopts="cookie=0x999, table=0, arp"
# ovs-ofctl -0 OpenFlow13 add-flow br0 \
"${ipflowopts}, nw_src=${TUNNEL_IP1}, actions=mod_nw_src:${RAMP_SDN_IP
},resubmit(,0)"
# ovs-ofctl -0 OpenFlow13 add-flow br0 \
"${ipflowopts}, nw_dst=${RAMP_SDN_IP}, actions=mod_nw_dst:${TUNNEL_IP1
}, resubmit(,0)"
# ovs-ofctl -0 OpenFlow13 add-flow br0 \
    "${arpflowopts}, arp_tpa=${RAMP_SDN_IP}, actions=output:2"
# ovs-ofctl -0 OpenFlow13 add-flow br0 \
    "${arpflowopts}, priority=200, in_port=2,
arp_spa=${RAMP_SDN_IP}, arp_tpa=${CLUSTER_NETWORK},
actions=goto_table:30"
# ovs-ofctl -0 OpenFlow13 add-flow br0 \
    "arp, table=5, priority=300, arp_tpa=${RAMP_SDN_IP},
actions=output:2"
# ovs-ofctl -0 OpenFlow13 add-flow br0 \
    "ip,table=5,priority=300,nw_dst=${RAMP_SDN_IP},actions=output:2"
# ovs-ofctl -0 OpenFlow13 add-flow br0
"${ipflowopts}, nw_dst=${TUNNEL_IP1}, actions=output:2"
```

7. Optionally, if you do not plan on configuring the ramp node to be highly available, mark the ramp node as unschedulable. Skip this step if you do plan to follow the next section and plan on creating a highly available ramp node.

\$ oadm manage-node <ramp_node_hostname> --schedulable=false

NOTE

The F5 router plug-in integrates with F5 BIG-IP®.

28.3.1. Configuring a Highly-Available Ramp Node

You can use OpenShift Container Platform's **ipfailover** feature, which uses **keepalived** internally, to make the ramp node highly available from **F5 BIG-IP®**'s point of view. To do so, first bring up two nodes, for example called **ramp-node-1** and **ramp-node-2**, on the same L2 subnet.

Then, choose some unassigned IP address from within the same subnet to use for your virtual IP, or VIP. This will be set as the RAMP_IP variable with which you will configure your tunnel on F5 BIG-IP®.

For example, suppose you are using the 10.20.30.0/24 subnet for your ramp nodes, and you have assigned 10.20.30.2 to ramp-node-1 and 10.20.30.3 to ramp-node-2. For your VIP, choose some unassigned address from the same 10.20.30.0/24 subnet, for example 10.20.30.4. Then, to configure ipfailover, mark both nodes with a label, such as f5rampnode:

```
$ oc label node ramp-node-1 f5rampnode=true
$ oc label node ramp-node-2 f5rampnode=true
```

Similar to instructions from the **ipfailover** documentation, you must now create a service account and add it to the **privileged** SCC. First, create the **f5ipfailover** service account:

```
$ oc create serviceaccount f5ipfailover -n default
```

Next, you can add the **f5ipfailover** service to the **privileged** SCC. To add the **f5ipfailover** in the **default** namespace to the **privileged** SCC, run:

```
$ oc adm policy add-scc-to-user privileged
system:serviceaccount:default:f5ipfailover
```

Finally, configure **ipfailover** using your chosen VIP (the **RAMP_IP** variable) and the **f5ipfailover** service account, assigning the VIP to your two nodes using the **f5rampnode** label you set earlier:

The interface where **RAMP_IP** should be configured.

With the above setup, the VIP (the RAMP_IP variable) is automatically re-assigned when the ramp node host that currently has it assigned fails.

CHAPTER 29. AGGREGATING CONTAINER LOGS

29.1. OVERVIEW

As an OpenShift Container Platform cluster administrator, you can deploy the EFK stack to aggregate logs for a range of OpenShift Container Platform services. Application developers can view the logs of the projects for which they have view access. The EFK stack aggregates logs from hosts and applications, whether coming from multiple containers or even deleted pods.

The EFK stack is a modified version of the ELK stack and is comprised of:

- Elasticsearch: An object store where all logs are stored.
- Fluentd: Gathers logs from nodes and feeds them to Elasticsearch.
- Kibana: A web UI for Elasticsearch.

Once deployed in a cluster, the stack aggregates logs from all nodes and projects into Elasticsearch, and provides a Kibana UI to view any logs. Cluster administrators can view all logs, but application developers can only view logs for projects they have permission to view. The stack components communicate securely.

NOTE

Managing Docker Container Logs discusses the use of json-file logging driver options to manage container logs and prevent filling node disks.

Aggregated logging is only supported using the **journald** driver in Docker. See Updating Fluentd's Log Source After a Docker Log Driver Update for more information.

29.2. PRE-DEPLOYMENT CONFIGURATION

- An Ansible playbook is available to deploy and upgrade aggregated logging. You should familiarize yourself with the advanced installation and configuration section. This provides information for preparing to use Ansible and includes information about configuration.
 Parameters are added to the Ansible inventory file to configure various areas of the EFK stack.
- 2. Review the sizing guidelines to determine how best to configure your deployment.
- 3. Ensure that you have deployed a router for the cluster.
- 4. Ensure that you have the necessary storage for Elasticsearch. Note that each Elasticsearch replica requires its own storage volume. See Elasticsearch for more information.
- 5. Choose a project. Once deployed, the EFK stack collects logs for every project within your OpenShift Container Platform cluster. The examples in this section use the default project logging. The Ansible playbook creates the project for you if it does not already exist. You will only need to create a project if you want to specify a node-selector on it. Otherwise, the openshift-logging role will create a project.

```
$ oadm new-project logging --node-selector=""
$ oc project logging
```

NOTE

Specifying an empty node selector on the project is recommended, as Fluentd should be deployed throughout the cluster and any selector would restrict where it is deployed. To control component placement, specify node selectors per component to be applied to their deployment configurations.

29.3. SPECIFYING LOGGING ANSIBLE VARIABLES

Parameters for the EFK deployment may be specified to the inventory host file to override the defaults. Read the Elasticsearch and the Fluentd sections before choosing parameters:

NOTE

By default the Elasticsearch service uses port 9300 for TCP communication between nodes in a cluster.

Parameter	Description
openshift_logging_im age_prefix	The prefix for logging component images. For example, setting the prefix to registry.access.redhat.com/openshift3/ creates registry.access.redhat.com/openshift3/logging-fluentd:latest.
openshift_logging_im age_version	The version for logging component images. For example, setting the version to v3.5 creates registry.access.redhat.com/openshift3/logging-fluentd:v3.5.
openshift_logging_us e_ops	If set to true , configures a second Elasticsearch cluster and Kibana for operations logs. Fluentd splits logs between the main cluster and a cluster reserved for operations logs (which consists of /var/log/messages on nodes and the logs from the projects default, openshift, and openshift-infra). This means a second Elasticsearch and Kibana are deployed. The deployments are distinguishable by the -ops suffix included in their names and have parallel deployment options listed below.
openshift_logging_ma ster_url	The URL for the Kubernetes master, this does not need to be public facing but should be accessible from within the cluster.
openshift_logging_ma ster_public_url	The public facing URL for the Kubernetes master. This is used for Authentication redirection by the Kibana proxy.
openshift_logging_na mespace	The namespace where Aggregated Logging will be deployed.
openshift_logging_in stall_logging	Set to true to install logging. Set to false to uninstall logging.
openshift_logging_im age_pull_secret	Specify the name of an existing pull secret to be used for pulling component images from an authenticated registry.

Parameter	Description
openshift_logging_cu rator_default_days	The default minimum age (in days) Curator uses for deleting log records.
openshift_logging_cu rator_run_hour	The hour of the day Curator will run.
openshift_logging_cu rator_run_minute	The minute of the hour Curator will run.
openshift_logging_cu rator_run_timezone	The timezone Curator uses for figuring out it's run time.
<pre>openshift_logging_cu rator_script_log_lev el</pre>	The script log level for Curator.
openshift_logging_cu rator_log_level	The log level for the Curator process.
openshift_logging_cu rator_cpu_limit	The amount of CPU to allocate to Curator.
openshift_logging_cu rator_memory_limit	The amount of memory to allocate to Curator.
openshift_logging_cu rator_nodeselector	A node selector that specifies which nodes are eligible targets for deploying Curator instances.
openshift_logging_cu rator_ops_cpu_limit	Equivalent to openshift_logging_curator_cpu_limit for Ops cluster when openshift_logging_use_ops is set to true.
<pre>openshift_logging_cu rator_ops_memory_lim it</pre>	Equivalent to openshift_logging_curator_memory_limit for Ops cluster when openshift_logging_use_ops is set to true.
openshift_logging_ki bana_hostname	The external host name for web clients to reach Kibana.
openshift_logging_ki bana_cpu_limit	The amount of CPU to allocate to Kibana.
openshift_logging_ki bana_memory_limit	The amount of memory to allocate to Kibana.
openshift_logging_ki bana_proxy_debug	When true , set the Kibana Proxy log level to DEBUG.

Parameter	Description
openshift_logging_ki bana_proxy_cpu_limit	The amount of CPU to allocate to Kibana proxy.
openshift_logging_ki bana_proxy_memory_li mit	The amount of memory to allocate to Kibana proxy.
openshift_logging_ki bana_replica_count	The number of replicas to which Kibana should be scaled up.
openshift_logging_ki bana_nodeselector	A node selector that specifies which nodes are eligible targets for deploying Kibana instances.
openshift_logging_ki bana_key	The public facing key to use when creating the kibana route.
openshift_logging_ki bana_cert	The cert that matches the key when creating the kibana route.
openshift_logging_ki bana_ca	Optional. The CA to goes with the key and cert used when creating the kibana route.
openshift_logging_ki bana_ops_hostname	Equivalent to openshift_logging_kibana_hostname for Ops cluster when openshift_logging_use_ops is set to true .
openshift_logging_ki bana_ops_cpu_limit	Equivalent to openshift_logging_kibana_cpu_limit for Ops cluster when openshift_logging_use_ops is set to true .
openshift_logging_ki bana_ops_memory_limi t	Equivalent to openshift_logging_kibana_memory_limit for Ops cluster when openshift_logging_use_ops is set to true .
openshift_logging_ki bana_ops_proxy_debug	Equivalent to openshift_logging_kibana_proxy_debug for Ops cluster when openshift_logging_use_ops is set to true .
openshift_logging_ki bana_ops_proxy_cpu_l imit	Equivalent to openshift_logging_kibana_proxy_cpu_limit for Ops cluster when openshift_logging_use_ops is set to true.
<pre>openshift_logging_ki bana_ops_proxy_memor y_limit</pre>	Equivalent to openshift_logging_kibana_proxy_memory_limit for Ops cluster when openshift_logging_use_ops is set to true.

Parameter	Description
openshift_logging_ki bana_ops_replica_cou nt	Equivalent to openshift_logging_kibana_replica_count for Ops cluster when openshift_logging_use_ops is set to true.
openshift_logging_fl uentd_nodeselector	A node selector that specifies which nodes are eligible targets for deploying Fluentd instances. Any node where Fluentd should run (typically, all) must have this label before Fluentd will be able to run and collect logs. When scaling up the Aggregated Logging cluster after installation, the openshift_logging role labels nodes provided by openshift_logging_fluentd_hosts with this node selector. As part of the installation, it is recommended that you add the Fluentd node selector label to the list of persisted node labels.
openshift_logging_fl uentd_cpu_limit	The CPU limit for Fluentd pods.
<pre>openshift_logging_fl uentd_memory_limit</pre>	The memory limit for Fluentd pods.
openshift_logging_fl uentd_use_journal	Set to true if Fluentd should read log entries from Journal. The default is empty space which will cause Fluentd to determine which log driver is being used.
<pre>openshift_logging_fl uentd_journal_read_f rom_head</pre>	Set to true if Fluentd should read from the head of Journal when first starting up, using this may cause a delay in ES receiving current log records.
openshift_logging_fl uentd_hosts	List of nodes that should be labeled for Fluentd to be deployed.
openshift_logging_es _host	The name of the ES service where Fluentd should send logs.
openshift_logging_es _port	The port for the ES service where Fluentd should send logs.
openshift_logging_es _ca	The location of the CA Fluentd uses to communicate with openshift_logging_es_host.
openshift_logging_es _client_cert	The location of the client certificate Fluentd uses for openshift_logging_es_host.
openshift_logging_es _client_key	The location of the client key Fluentd uses for openshift_logging_es_host.
openshift_logging_es _cluster_size	Elasticsearch replicas to deploy. Redundancy requires at least three or more.

Parameter	Description

openshift_logging_es _cpu_limit	The amount of CPU limit for the ES cluster.
openshift_logging_es _memory_limit	Amount of RAM to reserve per Elasticsearch instance. It must be at least 512M. Possible suffixes are G,g,M,m.
openshift_logging_es _pv_selector	A key/value map added to a PVC in order to select specific PVs.
openshift_logging_es _pvc_dynamic	If available for your cluster, set to true to have PVC claims annotated so that their backing storage is dynamically provisioned.
openshift_logging_es _pvc_size	Size of the persistent volume claim to create per ElasticSearch instance. For example, 100G. If omitted, no PVCs are created and ephemeral volumes are used instead.
openshift_logging_es _pvc_prefix	Prefix for the names of persistent volume claims to be used as storage for Elasticsearch instances. A number will be appended per instance, such as logging-es-1. If they do not already exist, they will be created with size es-pvc-size.
openshift_logging_es _recover_after_time	The amount of time ES will wait before it tries to recover.
openshift_logging_es _storage_group	Number of a supplemental group ID for access to Elasticsearch storage volumes. Backing volumes should allow access by this group ID.
openshift_logging_es _nodeselector	A node selector specified as a map that determines which nodes are eligible targets for deploying Elasticsearch instances. This can be used to place these instances on nodes reserved or optimized for running them. For example, the selector could be {"node-type": "infrastructure"}. At least one active node must have this label before Elasticsearch will deploy.
openshift_logging_es _ops_allow_cluster_r eader	Set to true if cluster-reader role is allowed to read operation logs.
openshift_logging_es _ops_host	Equivalent to openshift_logging_es_host for Ops cluster when openshift_logging_use_ops is set to true.
openshift_logging_es _ops_port	Equivalent to openshift_logging_es_port for Ops cluster when openshift_logging_use_ops is set to true.

Parameter	Description
openshift_logging_es _ops_ca	Equivalent to openshift_logging_es_ca for Ops cluster when openshift_logging_use_ops is set to true.
openshift_logging_es _ops_client_cert	Equivalent to openshift_logging_es_client_cert for Ops cluster when openshift_logging_use_ops is set to true.
openshift_logging_es _ops_client_key	Equivalent to openshift_logging_es_client_key for Ops cluster when openshift_logging_use_ops is set to true .
openshift_logging_es _ops_cluster_size	Equivalent to openshift_logging_es_cluster_size for Ops cluster when openshift_logging_use_ops is set to true .
openshift_logging_es _ops_cpu_limit	Equivalent to openshift_logging_es_cpu_limit for Ops cluster when openshift_logging_use_ops is set to true .
openshift_logging_es _ops_memory_limit	Equivalent to openshift_logging_es_memory_limit for Ops cluster when openshift_logging_use_ops is set to true.
openshift_logging_es _ops_pv_selector	Equivalent to openshift_logging_es_pv_selector for Ops cluster when openshift_logging_use_ops is set to true.
openshift_logging_es _ops_pvc_dynamic	Equivalent to openshift_logging_es_pvc_dynamic for Ops cluster when openshift_logging_use_ops is set to true.
openshift_logging_es _ops_pvc_size	Equivalent to openshift_logging_es_pvc_size for Ops cluster when openshift_logging_use_ops is set to true .
<pre>openshift_logging_es _ops_pvc_prefix</pre>	Equivalent to openshift_logging_es_pvc_prefix for Ops cluster when openshift_logging_use_ops is set to true .
openshift_logging_es _ops_recover_after_t ime	Equivalent to openshift_logging_es_recovery_after_time for Ops cluster when openshift_logging_use_ops is set to true.
openshift_logging_es _ops_storage_group	Equivalent to openshift_logging_es_storage_group for Ops cluster when openshift_logging_use_ops is set to true .
openshift_logging_es _ops_nodeselector	A node selector that specifies which nodes are eligible targets for deploying Elasticsearch instances. This can be used to place these instances on nodes reserved or optimized for running them. For example, the selector could be node-type=infrastructure . At least one active node must have this label before Elasticsearch will deploy.
openshift_logging_ki bana_ops_nodeselecto r	A node selector that specifies which nodes are eligible targets for deploying Kibana instances.

Parameter	Description
openshift_logging_cu rator_ops_nodeselect or	A node selector that specifies which nodes are eligible targets for deploying Curator instances.

29.4. DEPLOYING THE EFK STACK

The EFK stack is deployed using an Ansible playbook to the EFK components. Run the playbook from the default OpenShift Ansible location using the default inventory file.

```
$ ansible-playbook [-i </path/to/inventory>] \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
cluster/openshift-logging.yml
```

Running the playbook deploys all resources needed to support the stack; such as Secrets, ServiceAccounts, and DeploymentConfigs. The playbook waits to deploy the component pods until the stack is running. If the wait steps fail, the deployment could still be successful; it may be retrieving the component images from the registry which can take up to a few minutes. You can watch the process with:

\$ oc get pods -w

They will eventually enter **Running** status. For additional details about the status of the pods during deployment by retrieving associated events:

\$ oc describe pods/<pod_name>

Check the logs if the pods do not run successfully:

\$ oc logs -f <pod_name>

29.5. UNDERSTANDING AND ADJUSTING THE DEPLOYMENT

This section describes adjustments that you can make to deployed components.

29.5.1. Ops Cluster

NOTE

The logs for the **default**, **openshift**, and **openshift-infra** projects are automatically aggregated and grouped into the **.operations** item in the Kibana interface.

The project where you have deployed the EFK stack (**logging**, as documented here) is *not* aggregated into **.operations** and is found under its ID.

If you set openshift_logging_use_ops to true in your inventory file, Fluentd is configured to split logs between the main Elasticsearch cluster and another cluster reserved for operations logs, which are defined as node system logs and the projects default, openshift, and openshift-infra. Therefore, a separate Elasticsearch cluster, a separate Kibana, and a separate Curator are deployed to index,

access, and manage operations logs. These deployments are set apart with names that include **-ops**. Keep these separate deployments in mind if you enable this option. Most of the following discussion also applies to the operations cluster if present, just with the names changed to include **-ops**.

29.5.2. Elasticsearch

A highly-available environment requires at least three replicas of Elasticsearch; each on a different host. Elasticsearch replicas require their own storage, but an OpenShift Container Platform deployment configuration shares storage volumes between all its pods. So, when scaled up, the EFK deployer ensures each replica of Elasticsearch has its own deployment configuration.

It is possible to scale your cluster up after creation by modifying the openshift_logging_es_cluser_size in the inventory file and re-running the logging playbook. Additional clustering parameters can be modified and are described in Specifying Logging Ansible Variables.

Refer to Elastic's documentation for considerations involved in choosing storage and network location as directed below.

Viewing all Elasticsearch Deployments

To view all current Elasticsearch deployments:

\$ oc get dc --selector logging-infra=elasticsearch

Node Selector

Because Elasticsearch can use a lot of resources, all members of a cluster should have low latency network connections to each other and to any remote storage. Ensure this by directing the instances to dedicated nodes, or a dedicated region within your cluster, using a node selector.

To configure a node selector, specify the **openshift_logging_es_nodeselector** configuration option in the inventory file. This applies to all Elasticsearch deployments; if you need to individualize the node selectors, you must manually edit each deployment configuration after deployment. The node selector is specified as a python compatible dict. For example, {"node-type":"infra", "region":"east"}.

Persistent Elasticsearch Storage

By default, the openshift_logging Ansible role creates an ephemeral deployment in which all of a pod's data is lost upon restart. For production usage, specify a persistent storage volume for each Elasticsearch deployment configuration. You can create the necessary persistent volume claims before deploying or have them created for you. The PVCs must be named to match the openshift_logging_es_pvc_prefix setting, which defaults to logging-es-; each PVC name will have a sequence number added to it, so logging-es-1, logging-es-2, and so on. If a PVC needed for the deployment exists already, it is used; if not, and openshift_logging_es_pvc_size has been specified, it is created with a request for that size.

WARNING

Using NFS storage as a volume or a persistent volume (or via NAS such as Gluster) is not supported for Elasticsearch storage, as Lucene relies on file system behavior that NFS does not supply. Data corruption and other problems can occur. If NFS storage is a requirement, you can allocate a large file on a volume to serve as a storage device and mount it locally on one host. For example, if your NFS storage volume is mounted at /nfs/storage:

```
$ truncate -s 1T /nfs/storage/elasticsearch-1
$ mkfs.xfs /nfs/storage/elasticsearch-1
$ mount -o loop /nfs/storage/elasticsearch-1 /usr/local/es-
storage
$ chown 1000:1000 /usr/local/es-storage
```

Then, use /usr/local/es-storage as a host-mount as described below. Use a different backing file as storage for each Elasticsearch replica.

This loopback must be maintained manually outside of OpenShift Container Platform, on the node. You must not maintain it from inside a container.

It is possible to use a local disk volume (if available) on each node host as storage for an Elasticsearch replica. Doing so requires some preparation as follows.

1. The relevant service account must be given the privilege to mount and edit a local volume:

- Use the project you created earlier (for example, **logging**) when running the logging playbook.
- 2. Each Elasticsearch replica definition must be patched to claim that privilege, for example:

```
$ for dc in $(oc get deploymentconfig --selector logging-
infra=elasticsearch -o name); do
   oc scale $dc --replicas=0
   oc patch $dc \
       -p '{"spec":{"template":{"spec":{"containers":
[{"name":"elasticsearch", "securityContext":{"privileged":
true}}]}}}'
done
```

3. The Elasticsearch replicas must be located on the correct nodes to use the local storage, and should not move around even if those nodes are taken down for a period of time. This requires giving each Elasticsearch replica a node selector that is unique to a node where an

administrator has allocated storage for it. To configure a node selector, edit each Elasticsearch deployment configuration and add or edit the **nodeSelector** section to specify a unique label that you have applied for each desired node:

```
apiVersion: v1
kind: DeploymentConfig
spec:
template:
spec:
nodeSelector:
logging-es-node: "1" 1
```

This label should uniquely identify a replica with a single node that bears that label, in this case logging-es-node=1. Use the oc label command to apply labels to nodes as needed.

To automate applying the node selector you can instead use the **oc patch** command:

```
$ oc patch dc/logging-es-<suffix> \
    -p '{"spec":{"template":{"spec":{"nodeSelector":{"logging-es-node":"1"}}}}'
```

4. Once these steps are taken, a local host mount can be applied to each replica as in this example (where we assume storage is mounted at the same path on each node):

Changing the Scale of Elasticsearch

If you need to scale up the number of Elasticsearch instances your cluster uses, it is not as simple as scaling up an Elasticsearch deployment configuration. This is due to the nature of persistent volumes and how Elasticsearch is configured to store its data and recover the cluster. Instead, scaling up requires creating a deployment configuration for each Elasticsearch cluster node.

The simplest way to change the scale of Elasticsearch is to modify the inventory host file a re-run the logging playbook as desribed previously. Assuming you have supplied persistent storage for the deployment, this should not be disruptive.

If you do not wish to reinstall, for instance because you have made customizations that you would like to preserve, then it is possible to add new Elasticsearch deployment configurations to the cluster using a template supplied by the deployer. This requires a more complicated procedure however.

Allowing cluster-reader to view operations logs

By default, only cluster-admin users are granted access in Elasticsearch and Kibana to view operations logs. To allow cluster-reader users to also view these logs, update the value of openshift.operations.allow_cluster_reader in the Elasticsearch configmap to true:

\$ oc edit configmap/logging-elasticsearch

Please note that changes to the configmap might not appear until after redeploying the pods. Persisting these changes across deployments can be accomplished by setting openshift_logging_es_allows_cluster_reader to true in the inventory file.

29.5.3. Fluentd

Fluentd is deployed as a DaemonSet that deploys replicas according to a node label selector, which you can specify with the inventory parameter **openshift_logging_fluentd_nodeselector** and the default is **logging-infra-fluentd**. As part of the OpenShift cluster installation, it is recommended that you add the Fluentd node selector to the list of persisted node labels.

Having Fluentd Use the Systemd Journal as the Log Source

By default, Fluentd reads from /var/log/messages and /var/log/containers/<container>.log for system logs and container logs, respectively. You can instead use the systemd journal as the log source. There are three inventory parameters available:

Parameter	Description
openshift_logging_us e_journal	The default is empty, which configures Fluentd to check which log driver Docker is using. If Docker is usinglog-driver=journald, Fluentd reads from the systemd journal, otherwise, it assumes docker is using the json-file log driver and reads from the /var/log file sources. You can specify the openshift_logging_use_journal option as true or false to be explicit about which log source to use. Using the systemd journal requires docker-1.10 or later, and Docker must be configured to uselog-driver=journald. Aggregated logging is only supported using the journald driver in Docker. See Updating Fluentd's Log Source After a Docker Log Driver Update for more information.
openshift_logging_jo urnal_read_from_head	If this setting is false , Fluentd starts reading from the end of the journal, ignoring historical logs. If this setting is true , Fluentd starts reading logs from the beginning of the journal.

NOTE

As of OpenShift Container Platform 3.3, Fluentd no longer reads historical log files when using the JSON file log driver. In situations where clusters have a large number of log files and are older than the EFK deployment, this avoids delays when pushing the most recent logs into Elasticsearch. Curator deleting logs are migrated soon after they are added to Elasticsearch.

NOTE

It may require several minutes, or hours, depending on the size of your journal, before any new log entries are available in Elasticsearch, when using openshift_logging_journal_read_from_head=true.

WARNING

It is highly recommended that you use the default value for use-journal. In scenarios where upgrading OpenShift Container Platform changes the Docker log driver, if use-journal=False is explicitly specified as part of installation, Fluentd still expects to read logs generated using the json-file log driver. This results in a lack of log ingestion. If this has happened within your logging cluster, troubleshoot it.

Aggregated logging is only supported using the **journald** driver in Docker. See Updating Fluentd's Log Source After a Docker Log Driver Update for more information.

Having Fluentd Send Logs to Another Elasticsearch

NOTE

The use of **ES_COPY** is being deprecated. To configure FluentD to send a copy of its logs to an external aggregator, use Fluentd Secure Forward instead.

You can configure Fluentd to send a copy of each log message to both the Elasticsearch instance included with OpenShift Container Platform aggregated logging, and to an external Elasticsearch instance. For example, if you already have an Elasticsearch instance set up for auditing purposes, or data warehousing, you can send a copy of each log message to that Elasticsearch.

This feature is controlled via environment variables on Fluentd, which can be modified as described below.

If its environment variable **ES_COPY** is **true**, Fluentd sends a copy of the logs to another Elasticsearch. The names for the copy variables are just like the current **ES_HOST**, **OPS_HOST**, and other variables, except that they add **_COPY**: **ES_COPY_HOST**, **OPS_COPY_HOST**, and so on. There are some additional parameters added:

- ES_COPY_SCHEME, OPS_COPY_SCHEME can use either http or https defaults to https
- ES_COPY_USERNAME, OPS_COPY_USERNAME user name to use to authenticate to Elasticsearch using username/password auth
- ES_COPY_PASSWORD, OPS_COPY_PASSWORD password to use to authenticate to Elasticsearch using username/password auth

NOTE

Sending logs directly to an AWS Elasticsearch instance is not supported. Use Fluentd Secure Forward to direct logs to an instance of Fluentd that you control and that is configured with the fluent-plugin-aws-elasticsearch-service plug-in.

To set the parameters:

1. Edit the DaemonSet for Fluentd:

```
$ oc edit -n logging ds logging-fluentd
```

Add or edit the environment variable **ES_COPY** to have the value "true" (with the quotes), and add or edit the COPY variables listed above.

NOTE

These changes will not be persisted across multiple runs of the logging playbook. You will need to edit the DaemonSet each time to update environment variables.

Configuring Fluentd to Send Logs to an External Log Aggregator

You can configure Fluentd to send a copy of its logs to an external log aggregator, and not the default Elasticsearch, using the **secure-forward** plug-in. From there, you can further process log records after the locally hosted Fluentd has processed them.

The logging deployment provides a **secure-forward.conf** section in the Fluentd configmap for configuring the external aggregator:

```
<store>
@type secure_forward
self_hostname pod-${HOSTNAME}
shared_key thisisasharedkey
secure yes
enable_strict_verification yes
ca_cert_path /etc/fluent/keys/your_ca_cert
ca_private_key_path /etc/fluent/keys/your_private_key
ca_private_key_passphrase passphrase
<server>
 host ose1.example.com
  port 24284
</server>
<server>
  host ose2.example.com
  port 24284
  standby
</server>
<server>
  host ose3.example.com
  port 24284
  standby
</server>
</store>
```

This can be updated using the oc edit command:

```
$ oc edit configmap/logging-fluentd
```

Certificates to be used in secure-forward.conf can be added to the existing secret that is mounted on the Fluentd pods. The your_ca_cert and your_private_key values must match what is specified in secure-forward.conf in configmap/logging-fluentd:

```
$ oc patch secrets/logging-fluentd --type=json \
    --patch "[{'op':'add','path':'/data/your_ca_cert','value':'$(base64
/path/to/your_ca_cert.pem)'}]"
$ oc patch secrets/logging-fluentd --type=json \
    --patch "[{'op':'add','path':'/data/your_private_key','value':'$(base64
/path/to/your_private_key.pem)'}]"
```

When configuring the external aggregator, it must be able to accept messages securely from Fluentd.

If the external aggregator is another Fluentd process, it must have the **fluent-plugin-secure-forward** plug-in installed and make use of the input plug-in it provides:

Further explanation of how to set up the fluent-plugin-secure-forward plug-in can be found here

Throttling logs in Fluentd

For projects that are especially verbose, an administrator can throttle down the rate at which the logs are read in by Fluentd before being processed.

WARNING

Throttling can contribute to log aggregation falling behind for the configured projects; log entries can be lost if a pod is deleted before Fluentd catches up.

NOTE

Throttling does not work when using the systemd journal as the log source. The throttling implementation depends on being able to throttle the reading of the individual log files for each project. When reading from the journal, there is only a single log source, no log files, so no file-based throttling is available. There is not a method of restricting the log entries that are read into the Fluentd process.

To tell Fluentd which projects it should be restricting, edit the throttle configuration in its ConfigMap after deployment:

```
$ oc edit configmap/logging-fluentd
```

The format of the *throttle-config.yaml* key is a YAML file that contains project names and the desired rate at which logs are read in on each node. The default is 1000 lines at a time per node. For example:

```
logging:
    read_lines_limit: 500

test-project:
    read_lines_limit: 10

.operations:
    read_lines_limit: 100
```

29.5.4. Kibana

To access the Kibana console from the OpenShift Container Platform web console, add the loggingPublicURL parameter in the /etc/origin/master/master-config.yaml file, with the URL of the Kibana console (the kibana-hostname parameter). The value must be an HTTPS URL:

```
...
assetConfig:
...
loggingPublicURL: "https://kibana.example.com"
...
```

Setting the **loggingPublicURL** parameter creates a **View Archive** button on the OpenShift Container Platform web console under the **Browse** \rightarrow **Pods** \rightarrow **<pod_name>** \rightarrow **Logs** tab. This links to the Kibana console.

You can scale the Kibana deployment as usual for redundancy:

```
$ oc scale dc/logging-kibana --replicas=2
```

NOTE

To ensure the scale persists across multiple executions of the logging playbook, make sure to update the **openshift_logging_kibana_replica_count** in the inventory file.

You can see the user interface by visiting the site specified by the **openshift_logging_kibana_hostname** variable.

See the Kibana documentation for more information on Kibana.

29.5.5. Curator

Curator allows administrators to configure scheduled Elasticsearch maintenance operations to be performed automatically on a per-project basis. It is scheduled to perform actions daily based on its configuration. Only one Curator pod is recommended per Elasticsearch cluster. Curator is configured via a YAML configuration file with the following structure:

\$PROJECT_NAME:
\$ACTION:

\$UNIT: \$VALUE

\$PROJECT_NAME:
\$ACTION:

\$UNIT: \$VALUE

. . .

The available parameters are:

Variable Name	Description
\$PROJECT_NAME	The actual name of a project, such as myapp-devel. For OpenShift Container Platform operations logs, use the name . operations as the project name.
\$ACTION	The action to take, currently only delete is allowed.
\$UNIT	One of days, weeks, or months.
\$VALUE	An integer for the number of units.
.defaults	Use .defaults as the \$PROJECT_NAME to set the defaults for projects that are not specified.
runhour	(Number) the hour of the day in 24-hour format at which to run the Curator jobs. For use with .defaults.
runminute	(Number) the minute of the hour at which to run the Curator jobs. For use with .defaults.

For example, to configure Curator to:

- delete indices in the myapp-dev project older than 1 day
- delete indices in the myapp-qe project older than 1 week
- delete operations logs older than 8 weeks
- delete all other projects indices after they are 30 days old
- run the Curator jobs at midnight every day

Use:

myapp-dev: delete: days: 1

myapp-qe:

```
delete:
   weeks: 1

.operations:
   delete:
   weeks: 8

.defaults:
   delete:
    days: 30
   runhour: 0
   runminute: 0
```

IMPORTANT

When you use month as the \$UNIT for an operation, Curator starts counting at the first day of the current month, not the current day of the current month. For example, if today is April 15, and you want to delete indices that are 2 months older than today (delete: months: 2), Curator does not delete indices that are dated older than February 15; it deletes indices older than February 1. That is, it goes back to the first day of the current month, then goes back two whole months from that date. If you want to be exact with Curator, it is best to use days (for example, delete: days: 30).

29.5.5.1. Creating the Curator Configuration

The openshift_logging Ansible role provides a ConfigMap from which Curator reads its configuration. You may edit or replace this ConfigMap to reconfigure Curator. Currently the logging-curator ConfigMap is used to configure both your ops and non-ops Curator instances. Any .operations configurations will be in the same location as your application logs configurations.

1. To edit the provided ConfigMap to configure your Curator instances:

```
$ oc edit configmap/logging-curator
```

2. To replace the provided ConfigMap instead:

```
$ create /path/to/mycuratorconfig.yaml
$ oc create configmap logging-curator -o yaml \
    --from-file=config.yaml=/path/to/mycuratorconfig.yaml | \
    oc replace -f -
```

3. After you make your changes, redeploy Curator:

```
$ oc rollout latest dc/logging-curator
$ oc rollout latest dc/logging-curator-ops
```

29.6. CLEANUP

Remove everything generated during the deployment.

```
$ ansible-playbook [-i </path/to/inventory>] \
/usr/share/ansible/openshift-ansible/playbooks/common/openshift-
cluster/openshift_logging.yml \
```

-e openshift_logging_install_logging=False

29.7. TROUBLESHOOTING KIBANA

Using the Kibana console with OpenShift Container Platform can cause problems that are easily solved, but are not accompanied with useful error messages. Check the following troubleshooting sections if you are experiencing any problems when deploying Kibana on OpenShift Container Platform:

Login Loop

The OAuth2 proxy on the Kibana console must share a secret with the master host's OAuth2 server. If the secret is not identical on both servers, it can cause a login loop where you are continuously redirected back to the Kibana login page.

To fix this issue, delete the current OAuthClient, and use **openshift-ansible** to re-run the **openshift_logging** role:

```
$ oc delete oauthclient/kibana-proxy
$ ansible-playbook [-i </path/to/inventory>] \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
cluster/openshift-logging.yml
```

Cryptic Error When Viewing the Console

When attempting to visit the Kibana console, you may receive a browser error instead:

```
{"error":"invalid_request", "error_description":"The request is missing a required parameter, includes an invalid parameter value, includes a parameter more than once, or is otherwise malformed."}
```

This can be caused by a mismatch between the OAuth2 client and server. The return address for the client must be in a whitelist so the server can securely redirect back after logging in.

Fix this issue by replacing the OAuthClient entry:

```
$ oc delete oauthclient/kibana-proxy
$ ansible-playbook [-i </path/to/inventory>] \
    /usr/share/ansible/openshift-ansible/playbooks/byo/openshift-
cluster/openshift-logging.yml
```

If the problem persists, check that you are accessing Kibana at a URL listed in the OAuth client. This issue can be caused by accessing the URL at a forwarded port, such as 1443 instead of the standard 443 HTTPS port. You can adjust the server whitelist by editing the OAuth client:

```
$ oc edit oauthclient/kibana-proxy
```

503 Error When Viewing the Console

If you receive a proxy error when viewing the Kibana console, it could be caused by one of two issues.

First, Kibana may not be recognizing pods. If Elasticsearch is slow in starting up, Kibana may timeout trying to reach it. Check whether the relevant service has any endpoints:

\$ oc describe service logging-kibana
Name: logging-kibana

 $[\ldots]$

Endpoints: <none>

If any Kibana pods are live, endpoints will be listed. If they are not, check the state of the Kibana pods and deployment. You may need to scale the deployment down and back up again.

The second possible issue may be caused if the route for accessing the Kibana service is masked. This can happen if you perform a test deployment in one project, then deploy in a different project without completely removing the first deployment. When multiple routes are sent to the same destination, the default router will only route to the first created. Check the problematic route to see if it is defined in multiple places:

\$ oc get route --all-namespaces --selector logging-infra=support

F-5 Load Balancer and X-Forwarded-For Enabled

If you are attempting to use a F-5 load balancer in front of Kibana with X-Forwarded-For enabled, this can cause an issue in which the Elasticsearch Searchguard plug-in is unable to correctly accept connections from Kibana.

Example Kibana Error Message

Kibana: Unknown error while connecting to Elasticsearch

Error: Unknown error while connecting to Elasticsearch

Error: UnknownHostException[No trusted proxies]

To configure Searchquard to ignore the extra header:

- 1. Scale down all Fluentd pods.
- 2. Scale down Elasticsearch after the Fluentd pods have terminated.
- 3. Add searchguard.http.xforwardedfor.header: DUMMY to the Elasticsearch configuration section.
 - \$ oc edit configmap/logging-elasticsearch 1
 - 1 This approach requires that Elasticsearch's configurations are within a ConfigMap.
- 4. Scale Elasticsearch back up.
- 5. Scale up all Fluentd pods.

29.8. SENDING LOGS TO AN EXTERNAL ELASTICSEARCH INSTANCE

Fluentd sends logs to the value of the ES_HOST, ES_PORT, OPS_HOST, and OPS_PORT environment variables of the Elasticsearch deployment configuration. The application logs are directed to the ES_HOST destination, and operations logs to OPS_HOST.

NOTE

Sending logs directly to an AWS Elasticsearch instance is not supported. Use Fluentd Secure Forward to direct logs to an instance of Fluentd that you control and that is configured with the fluent-plugin-aws-elasticsearch-service plug-in.

To direct logs to a specific Elasticsearch instance, edit the deployment configuration and replace the value of the above variables with the desired instance:

\$ oc edit dc/<deployment_configuration>

For an external Elasticsearch instance to contain both application and operations logs, you can set ES_HOST and OPS_HOST to the same destination, while ensuring that ES_PORT and OPS_PORT also have the same value.

If your externally hosted Elasticsearch instance does not use TLS, update the _CLIENT_CERT, _CLIENT_KEY, and _CA variables to be empty. If it does use TLS, but not mutual TLS, update the _CLIENT_CERT and _CLIENT_KEY variables to be empty and patch or recreate the <code>logging-fluentd</code> secret with the appropriate _CA value for communicating with your Elasticsearch instance. If it uses Mutual TLS as the provided Elasticsearch instance does, patch or recreate the <code>logging-fluentd</code> secret with your client key, client cert, and CA.

NOTE

If you are not using the provided Kibana and Elasticsearch images, you will not have the same multi-tenant capabilities and your data will not be restricted by user access to a particular project.

29.9. PERFORMING ADMINISTRATIVE ELASTICSEARCH OPERATIONS

As of logging version 3.2.0, an administrator certificate, key, and CA that can be used to communicate with and perform administrative operations on Elasticsearch are provided within the **logging-elasticsearch** secret.

NOTE

To confirm whether or not your EFK installation provides these, run:

\$ oc describe secret logging-elasticsearch

If they are not available, refer to Manual Upgrades to ensure you are on the latest version first.

- 1. Connect to an Elasticsearch pod that is in the cluster on which you are attempting to perform maintenance.
- 2. To find a pod in a cluster use either:

```
$ oc get pods -l component=es -o name | head -1
$ oc get pods -l component=es-ops -o name | head -1
```

+ 00 900 pouc + 00mponone 00 ope 0 name 1 nour

3. Connect to a pod:

```
$ oc rsh <your_Elasticsearch_pod>
```

 Once connected to an Elasticsearch container, you can use the certificates mounted from the secret to communicate with Elasticsearch per its Indices APIs documentation.

Fluentd sends its logs to Elasticsearch using the index format project_qroject_name. {project_uuid}.YYYY.MM.DD where YYYY.MM.DD is the date of the log record.

For example, to delete all logs for the **logging** project with uuid **3b3594fa-2ccd-11e6-acb7-0eb6b35eaee3** from June 15, 2016, we can run:

```
$ curl --key /etc/elasticsearch/secret/admin-key \
    --cert /etc/elasticsearch/secret/admin-cert \
    --cacert /etc/elasticsearch/secret/admin-ca -XDELETE \
    "https://localhost:9200/project.logging.3b3594fa-2ccd-11e6-acb7-
0eb6b35eaee3.2016.06.15"
```

29.10. UPDATING FLUENTD'S LOG SOURCE AFTER A DOCKER LOG DRIVER UPDATE

If the Docker log driver has changed from <code>json-file</code> to <code>journald</code> and Fluentd was previously configured with <code>USE_JOURNAL=False</code>, then it will not be able to pick up any new logs that are created. When the Fluentd daemonset is configured with the default value for <code>USE_JOURNAL</code>, then it will detect the Docker log driver upon pod start-up, and configure itself to pull from the appropriate source.

To update Fluentd to detect the correct source upon start-up:

1. Remove the label from nodes where Fluentd is deployed:

```
$ oc label node --all logging-infra-fluentd- 1
```

2. Update the daemonset/logging-fluentd USE_JOURNAL value to be empty:

```
$ oc patch daemonset/logging-fluentd \
    -p '{"spec":{"template":{"spec":{"containers":
[{"name":"fluentd-elasticsearch", "env":[{"name": "USE_JOURNAL",
"value":""}]}}}}'
```

3. Relabel your nodes to schedule Fluentd deployments:

```
$ oc label node --all logging-infra-fluentd=true 1
```

This example assumes use of the default Fluentd node selector and it being deployed on all nodes.

CHAPTER 30. AGGREGATE LOGGING SIZING GUIDELINES

30.1. OVERVIEW

The Elasticsearch, Fluentd, and Kibana (EFK) stack aggregates logs from nodes and applications running inside your OpenShift Container Platform installation. Once deployed it uses Fluentd to aggregate event logs from all nodes, projects, and pods into Elasticsearch (ES). It also provides a centralized Kibana web UI where users and administrators can create rich visualizations and dashboards with the aggregated data.

Fluentd bulk uploads logs to an index, in JSON format, then Elasticsearch routes your search requests to the appropriate shards.

30.2. INSTALLATION

The general procedure for installing an aggregate logging stack in OpenShift Container Platform is described in Aggregating Container Logs. There are some important things to keep in mind while going through the installation guide:

In order for the logging pods to spread evenly across your cluster, an empty node selector should be used.

```
$ oadm new-project logging --node-selector=""
```

In conjunction with node labeling, which is done later, this controls pod placement across the logging project. You can now create the logging project.

```
$ oc project logging
```

Elasticsearch (ES) should be deployed with a cluster size of at least three for resiliency to node failures. This is specified by setting the **openshift_logging_es_cluster_size** parameter in the inventory host file.

Refer to Ansible Variables for a full list of parameters.

If you do not have an existing Kibana installation, you can use **kibana.example.com** as a value to **openshift_logging_kibana_hostname**.

Installation can take some time depending on whether the images were already retrieved from the registry or not, and on the size of your cluster.

Inside the logging namespace, you can check your deployment with oc get all.

\$ oc get all

	•			

By default the amount of RAM allocated to each ES instance is 8GB.

openshift_logging_es_memory_limit is the parameter used in the openshift-ansible host inventory file. Keep in mind that half of this value will be passed to the individual elasticsearch pods java processes heap size.

Learn more about installing EFK.

30.2.1. Large Clusters

At 100 nodes or more, it is recommended to pre-pull the logging images first and to set **ImagePullPolicy: IfNotPresent** in the *logging-deployer.yaml* file. After deploying the logging infrastructure pods (Elasticsearch, Kibana and Curator), node labeling should be done in steps of 20 nodes at a time. For example:

Using a simple loop:

```
$ while read node; do oc label nodes $node logging-infra-fluentd=true;
done < 20_fluentd.lst</pre>
```

The following also works:

```
$ oc label nodes 10.10.0.{100..119} logging-infra-fluentd=true
```

Labeling nodes in groups paces the DaemonSets used by OpenShift logging, helping to avoid contention on shared resources such as the image registry.

NOTE

Check for the occurence of any "CrashLoopBackOff | ImagePullFailed | Error" issues. oclogs <pod>, oc describe pod <pod> and oc get event are helpful diagnostic commands.

30.3. SYSTEMD-JOURNALD AND RSYSLOG

Rate-limiting

In Red Hat Enterprise Linux (RHEL) 7 the **systemd-journald.socket** unit creates **/dev/log** during the boot process, and then passes input to **systemd-journald.service**. Every **syslog()** call goes to the journal.

Rsyslog uses the **imjournal** module as a default input mode for journal files. Refer to Interaction of rsyslog and journal for detailed information about this topic.

A simple test harness was developed, which uses logger across the cluster nodes to make entries of different sizes at different rates in the system log. During testing simulations under a default Red Hat Enterprise Linux (RHEL) 7 installation with systemd-219-19.el7.x86_64 at certain logging rates (approximately 40 log lines per second), we encountered the default rate limit of rsyslogd. After adjusting these limits, entries stopped being written to journald due to local journal file corruption. This issue is resolved in later versions of systemd.

Scaling up

As you scale up your project, the default logging environment might need some adjustments. After updating to systemd-219-22.el7.x86_64, we added:

\$IMUXSockRateLimitInterval 0 \$IMJournalRatelimitInterval 0

to /etc/rsyslog.conf and:

Disable rate limiting
RateLimitInterval=1s
RateLimitBurst=10000
Storage=volatile
Compress=no
MaxRetentionSec=5s

to /etc/systemd/journald.conf.

Now, restart the services.

```
$ systemctl restart systemd-journald.service
$ systemctl restart rsyslog.service
```

These settings account for the bursty nature of uploading in bulk.

After removing the rate limit, you may see increased CPU utilization on the system logging daemons as it processes any messages that would have previously been throttled.

Rsyslog is configured (see **ratelimit.interval**, **ratelimit.burst**) to rate-limit entries read from the journal at 10,000 messages in 300 seconds. A good rule of thumb is to ensure that the rsyslog ratelimits account for the systemd-journald rate-limits.

30.4. SCALING UP EFK LOGGING

If you do not indicate the desired scale at first deployment, the least disruptive way of adjusting your cluster is by re-running the Ansible logging playbook after updating the inventory file with an updated openshift_logging_es_cluster_size value. parameter. Refer to the Performing Administrative Elasticsearch Operations section for more in-depth information.

30.5. STORAGE CONSIDERATIONS

An Elasticsearch index is a collection of shards and its corresponding replica shards. This is how ES implements high availability internally, therefore there is little need to use hardware based mirroring RAID variants. RAID 0 can still be used to increase overall disk performance.

Every search request needs to hit a copy of every shard in the index. Each ES instance requires its own individual storage, but an OpenShift Container Platform deployment can only provide volumes shared by all of its pods, which again means that Elasticsearch shouldn't be implemented with a single node.

A persistent volume should be added to each Elasticsearch deployment configuration so that we have one volume per replica shard. On OpenShift Container Platform this is often achieved through Persistent Volume Claims

- 1 volume per shard
- 1 volume per replica shard

The PVCs must be named based on the openshift_logging_es_pvc_prefix setting. Refer to Persistent Elasticsearch Storage for more details.

Below are capacity planning guidelines for OpenShift Container Platform aggregate logging. **Example scenario**

Assumptions:

1. Which application: Apache

2. Bytes per line: 256

3. Lines per second load on application: 1

4. Raw text data → JSON

Baseline (256 characters per minute \rightarrow 15KB/min)

Logging Infra Pods	Storage Throughput
3 es 1 kibana 1 curator 1 fluentd	6 pods total: 90000 x 86400 = 7,7 GB/day
3 es 1 kibana 1 curator 11 fluentd	16 pods total: 225000 x 86400 = 24,0 GB/day
3 es 1 kibana 1 curator 20 fluentd	25 pods total: 225000 x 86400 = 32,4 GB/day

Calculating total logging throughput and disk space required for your logging environment requires knowledge of your application. For example, if one of your applications on average logs 10 lines-persecond, each 256 bytes-per-line, calculate per-application throughput and disk space as follows:

```
(bytes-per-line * (lines-per-second) = 2560 bytes per app per second
(2560) * (number-of-pods-per-node,100) = 256,000 bytes per second per node
256k * (number-of-nodes) = total logging throughput per cluster
```

Fluentd ships any logs from /var/log/messages and /var/lib/docker/containers/ to Elasticsearch. Learn more.

Local SSD drives are recommended in order to achieve the best performance. In Red Hat Enterprise Linux (RHEL) 7, the deadline IO scheduler is the default for all block devices except SATA disks. For SATA disks, the default IO scheduler is cfq.

Sizing storage for ES is greatly dependent on how you optimize your indices. Therefore, consider how much data you need in advance and that you are aggregating application log data. Some Elasticsearch users have found that it is necessary to keep absolute storage consumption around 50% and below 70% at all times. This helps to avoid Elasticsearch becoming unresponsive during large merge operations.

CHAPTER 31. ENABLING CLUSTER METRICS

31.1. OVERVIEW

The kubelet exposes metrics that can be collected and stored in back-ends by Heapster.

As an OpenShift Container Platform administrator, you can view a cluster's metrics from all containers and components in one user interface. These metrics are also used by horizontal pod autoscalers in order to determine when and how to scale.

This topic describes using Hawkular Metrics as a metrics engine which stores the data persistently in a Cassandra database. When this is configured, CPU, memory and network-based metrics are viewable from the OpenShift Container Platform web console and are available for use by horizontal pod autoscalers.

Heapster retrieves a list of all nodes from the master server, then contacts each node individually through the /stats endpoint. From there, Heapster scrapes the metrics for CPU, memory and network usage, then exports them into Hawkular Metrics.

Browsing individual pods in the web console displays separate sparkline charts for memory and CPU. The time range displayed is selectable, and these charts automatically update every 30 seconds. If there are multiple containers on the pod, then you can select a specific container to display its metrics.

If resource limits are defined for your project, then you can also see a donut chart for each pod. The donut chart displays usage against the resource limit. For example: 145 Available of 200 MiB, with the donut chart showing 55 MiB Used.

31.2. BEFORE YOU BEGIN

An Ansible playbook is available to deploy and upgrade cluster metrics. You should familiarize yourself with the Advanced Installation section. This provides information for prepairing to use Ansible and includes information about configuration. Parameters are added to the Ansible inventory file to configure various areas of cluster metrics.

The following describe the various areas and the parameters that can be added to the Ansible inventory file in order to modify the defaults:

- Metrics Project
- Metrics Data Storage

31.3. METRICS PROJECT

The components for cluster metrics must be deployed to the **openshift-infra** project in order for autoscaling to work. Horizontal pod autoscalers specifically use this project to discover the Heapster service and use it to retrieve metrics. The metrics project can be changed by adding **openshift_metrics_project** to the inventory file.

31.4. METRICS DATA STORAGE

You can store the metrics data to either persistent storage or to a temporary pod volume.

31.4.1. Persistent Storage

Running OpenShift Container Platform cluster metrics with persistent storage means that your metrics will be stored to a persistent volume and be able to survive a pod being restarted or recreated. This is ideal if you require your metrics data to be guarded from data loss. For production environments it is highly recommended to configure persistent storage for your metrics pods.

The size requirement of the Cassandra storage is dependent on the number of pods. It is the administrator's responsibility to ensure that the size requirements are sufficient for their setup and to monitor usage to ensure that the disk does not become full. The size of the persisted volume claim is specified with the <code>openshift_metrics_cassandra_pvc_size</code> which is set to 10 GB by default.

If you would like to use dynamically provisioned persistent volumes set the openshift_metrics_cassandra_storage_typevariable to dynamic in the inventory file.

31.4.2. Capacity Planning for Cluster Metrics

After running the **openshift_metrics** Ansible role, the output of **oc get pods** should resemble the following:

# oc get pods -n openshift-infra		
NAME	READY	STATUS
RESTARTS AGE		
hawkular-cassandra-1-l5y4g	1/1	Running 0
17h		
hawkular-metrics-1t9so	1/1	Running 0
17h		
heapster-febru	1/1	Running 0
17h		

OpenShift Container Platform metrics are stored using the Cassandra database, which is deployed with settings of openshift_metrics_cassandra_limits_memory: 2G; this value could be adjusted further based upon the available memory as determined by the Cassandra start script. This value should cover most OpenShift Container Platform metrics installations, but using environment variables you can modify the MAX_HEAP_SIZE along with heap new generation size, HEAP_NEWSIZE, in the Cassandra Dockerfile prior to deploying cluster metrics.

By default, metrics data is stored for seven days. After seven days, Cassandra begins to purge the oldest metrics data. Metrics data for deleted pods and projects is not automatically purged; it is only removed once the data is more than seven days old.

Example 31.1. Data Accumulated by 10 Nodes and 1000 Pods

In a test scenario including 10 nodes and 1000 pods, a 24 hour period accumulated 2.5 GB of metrics data. Therefore, the capacity planning formula for metrics data in this scenario is:

$$(((2.5 \times 10^9) \div 1000) \div 24) \div 10^6 = \sim 0.125 \text{ MB/hour per pod.}$$

Example 31.2. Data Accumulated by 120 Nodes and 10000 Pods

In a test scenario including 120 nodes and 10000 pods, a 24 hour period accumulated 25 GB of metrics data. Therefore, the capacity planning formula for metrics data in this scenario is:

$$(((11.410 \times 10^9) \div 1000) \div 24) \div 10^6 = 0.475 \text{ MB/hour}$$

	1000 pods	10000 pods
Cassandra storage data accumulated over 24 hours (default metrics parameters)	2.5 GB	11.4 GB

If the default value of 7 days for openshift_metrics_duration and 10 seconds for openshift_metrics_resolution are preserved, then weekly storage requirements for the Cassandra pod would be:

	1000 pods	10000 pods
Cassandra storage data accumulated over seven days (default metrics parameters)	20 GB	90 GB

In the previous table, an additional 10 percent was added to the expected storage space as a buffer for unexpected monitored pod usage.

WARNING

If the Cassandra persisted volume runs out of sufficient space, then data loss will

For cluster metrics to work with persistent storage, ensure that the persistent volume has the **ReadWriteOnce** access mode. If this mode is not active, then the persistent volume claim cannot locate the persistent volume, and Cassandra fails to start.

To use persistent storage with the metric components, ensure that a persistent volume of sufficient size is available. The creation of persistent volume claims is handled by the OpenShift Ansible openShift_metrics role.

OpenShift Container Platform metrics also supports dynamically-provisioned persistent volumes. To use this feature with OpenShift Container Platform metrics, it is necessary to set the value of openshift_metrics_cassandra_storage_type to dynamic. You can use EBS, GCE, and Cinder storage back-ends to dynamically provision persistent volumes.

For information on configuring the performance and scaling the cluster metrics pods, see the Scaling Cluster Metrics topic.

Table 31.1. Cassandra Database storage requirements based on number of nodes/pods in the cluster

Number of Nodes	Number of Pods	Cassandra Storage growth speed	Cassandra storage growth per day	Cassandra storage growth per week
210	10500	500 MB per hour	15 GB	75 GB
990	11000	1 GB per hour	30 GB	210 GB

In the above calculation, approximately 20 percent of the expected size was added as overhead to ensure that the storage requirements do not exceed calculated value.

If the METRICS_DURATION and METRICS_RESOLUTION values are kept at the default (7 days and 15 seconds respectively), it is safe to plan Cassandra storage size requrements for week, as in the values above.

WARNING

Because OpenShift Container Platform metrics uses the Cassandra database as a datastore for metrics data, if USE_PERSISTANT_STORAGE=true is set during the metrics set up process, PV will be on top in the network storage, with NFS as the default. However, using network storage in combination with Cassandra is not recommended, as per the Cassandra documentation.

Recommendations for OpenShift Container Platform Version 3.5

- Run metrics pods on dedicated OpenShift Container Platform infrastructure nodes.
- Use persistent storage when configuring metrics. Set USE_PERSISTENT_STORAGE=true.
- Keep the METRICS_RESOLUTION=30 parameter in OpenShift Container Platform metrics deployments. Using a value lower than the default value of 30 for METRICS_RESOLUTION is not recommended. When using the Ansible metrics installation procedure, this is the openshift_metrics_resolution parameter.
- Closely monitor OpenShift Container Platform nodes with host metrics pods to detect early capacity shortages (CPU and memory) on the host system. These capacity shortages can cause problems for metrics pods.
- In OpenShift Container Platform version 3.5 testing, test cases up to 25,000 pods were monitored in a OpenShift Container Platform cluster.

Known Issues and Limitations

Testing found that the **heapster** metrics component is capable of handling up to 25,000 pods. If the amount of pods exceed that number, Heapster begins to fall behind in metrics processing, resulting in the possibility of metrics graphs no longer appearing. Work is ongoing to increase the number of pods that Heapster can gather metrics on, as well as upstream development of alternate metrics-gathering solutions.

31.4.3. Non-Persistent Storage

Running OpenShift Container Platform cluster metrics with non-persistent storage means that any stored metrics will be deleted when the pod is deleted. While it is much easier to run cluster metrics with non-persistent data, running with non-persistent data does come with the risk of permanent data loss. However, metrics can still survive a container being restarted.

In order to use non-persistent storage, you must set the openshift_metrics_cassandra_storage_typevariable to emptydir in the inventory file.

NOTE

When using non-persistent storage, metrics data will be written to /var/lib/origin/openshift.local.volumes/pods on the node where the Cassandra pod is running. Ensure /var has enough free space to accommodate metrics storage.

31.5. METRICS ANSIBLE ROLE

The OpenShift Ansible openshift_metrics role configures and deploys all of the metrics components using the variables from the Configuring Ansible inventory file.

31.5.1. Specifying Metrics Ansible Variables

The openshift_metrics role included with OpenShift Ansible defines the tasks to deploy cluster metrics. The following is a list of role variables that can be added to your inventory file if it is necessary to override them.

Table 31.2. Ansible Variables

Variable	Description
openshift_metrics_install_metrics	Deploy metrics if true . Otherwise, undeploy.
openshift_metrics_start_cluster	Start the metrics cluster after deploying the components.
openshift_metrics_image_prefix	The prefix for the component images. With openshift3/ose-metrics-cassandra:3.5.0, set prefix openshift/ose For example, for openshift3/ose-metrics-cassandra:3.5.0, set 3.5.0, or to always get the latest 3.5 image, set v3.5.
openshift_metrics_image_version	The version for the component images. For example, with openshift3/ose-metrics-cassandra:3.5.0, set version as 3.5.0, or to always get the latest 3.5 image, set v3.5.
openshift_metrics_startup_timeout	The time, in seconds, to wait until Hawkular Metrics and Heapster start up before attempting a restart.

Variable	Description
openshift_metrics_duration	The number of days to store metrics before they are purged.
openshift_metrics_resolution	The frequency that metrics are gathered. Defined as a number and time identifier: seconds (s), minutes (m), hours (h).
<pre>openshift_metrics_cassandra_pvc_pref ix</pre>	The persistent volume claim prefix created for Cassandra. A serial number is appended to the prefix starting from 1.
openshift_metrics_cassandra_pvc_size	The persistent volume claim size for each of the Cassandra nodes.
openshift_metrics_cassandra_storage_ type	Use emptydir for ephemeral storage (for testing); pv for persistent volumes, which need to be created before the installation; or dynamic for dynamic persistent volumes.
openshift_metrics_cassandra_replicas	The number of Cassandra nodes for the metrics stack. This value dictates the number of Cassandra replication controllers.
<pre>openshift_metrics_cassandra_limits_m emory</pre>	The memory limit for the Cassandra pod. For example, a value of 2Gi would limit Cassandra to 2 GB of memory. This value could be further adjusted by the start script based on available memory of the node on which it is scheduled.
openshift_metrics_cassandra_limits_c pu	The CPU limit for the Cassandra pod. For example, a value of 4000m (4000 millicores) would limit Cassandra to 4 CPUs.
openshift_metrics_cassandra_replicas	The number of replicas for Cassandra.
openshift_metrics_cassandra_requests _memory	The amount of memory to request for Cassandra pod. For example, a value of 2Gi would request 2 GB of memory.
openshift_metrics_cassandra_requests _cpu	The CPU request for the Cassandra pod. For example, a value of 4000m (4000 millicores) would request 4 CPUs.
openshift_metrics_cassandra_storage_ group	The supplemental storage group to use for Cassandra.

Variable	Description
openshift_metrics_hawkular_ca	An optional certificate authority (CA) file used to sign the Hawkular certificate.
openshift_metrics_hawkular_cert	The certificate file used for re-encrypting the route to Hawkular metrics. The certificate must contain the host name used by the route. If unspecified, the default router certificate is used.
openshift_metrics_hawkular_key	The key file used with the Hawkular certificate.
openshift_metrics_hawkular_limits_me mory	The amount of memory to limit the Hawkular pod. For example, a value of 2Gi would limit the Hawkular pod to 2 GB of memory. This value could be further adjusted by the start script based on available memory of the node on which it is scheduled.
openshift_metrics_hawkular_limits_cp u	The CPU limit for the Hawkular pod. For example, a value of 4000m (4000 millicores) would limit the Hawkular pod to 4 CPUs.
openshift_metrics_hawkular_replicas	The number of replicas for Hawkular metrics.
openshift_metrics_hawkular_requests_ memory	The amount of memory to request for the Hawkular pod. For example, a value of 2Gi would request 2 GB of memory.
openshift_metrics_hawkular_requests_ cpu	The CPU request for the Hawkular pod. For example, a value of 4000m (4000 millicores) would request 4 CPUs.
openshift_metrics_heapster_allowed_u sers	A comma-separated list of CN to accept. By default, this is set to allow the OpenShift service proxy to connect. Add system:master-proxy to the list when overriding in order to allow horizontal pod autoscaling to function properly.
openshift_metrics_heapster_limits_me mory	The amount of memory to limit the Heapster pod. For example, a value of 2Gi would limit the Heapster pod to 2 GB of memory.
openshift_metrics_heapster_limits_cp u	The CPU limit for the Heapster pod. For example, a value of 4000m (4000 millicores) would limit the Heapster pod to 4 CPUs.
openshift_metrics_heapster_requests_ memory	The amount of memory to request for Heapster pod. For example, a value of 2Gi would request 2 GB of memory.

Variable	Description
openshift_metrics_heapster_requests_ cpu	The CPU request for the Heapster pod. For example, a value of 4000m (4000 millicores) would request 4 CPUs.
openshift_metrics_heapster_standalon e	Deploy only Heapster, without the Hawkular Metrics and Cassandra components.

See Compute Resources for for further discussion on how to specify requests and limits.

The only required variable is openshift_metrics_hawkular_hostname. This value is required when executing the openshift_metrics Ansible role because it uses the host name for the Hawkular Metrics route. This value should correspond to a fully qualified domain name. You must know the value of openshift_metrics_hawkular_hostname when configuring the console for metrics access.

If you are using persistent storage with Cassandra, it is the administrator's responsibility to set a sufficient disk size for the cluster using the openshift_metrics_cassandra_pvc_size variable. It is also the administrator's responsibility to monitor disk usage to make sure that it does not become full.

WARNING

Data loss will result if the Cassandra persisted volume runs out of sufficient space.

All of the other variables are optional and allow for greater customization. For instance, if you have a custom install in which the Kubernetes master is not available under https://kubernetes.default.svc:443 you can specify the value to use instead with the openshift_metrics_master_url parameter. To deploy a specific version of the metrics components, modify the openshift_metrics_image_version variable.

WARNING

It is highly recommended to not use latest for the openshift_metrics_image_version. The latest version corresponds to the very latest version available and can cause issues if it brings in a newer version not meant to function on the version of OpenShift Container Platform you are currently running.

31.5.2. Using Secrets

The OpenShift Ansible openshift_metrics role will auto-generate self-signed certificates for use between its components and will generate a re-encrypting route to expose the Hawkular Metrics service. This route is what allows the web console to access the Hawkular Metrics service.

In order for the browser running the web console to trust the connection through this route, it must trust the route's certificate. This can be accomplished by providing your own certificates signed by a trusted Certificate Authority. The openshift_metrics role allows you to specify your own certificates which it will then use when creating the route.

The router's default certificate are used if you do not provide your own.

31.5.2.1. Providing Your Own Certificates

To provide your own certificate which will be used by the re-encrypting route, you can set the openshift_metrics_hawkular_cert, openshift_metrics_hawkular_key, and openshift_metrics_hawkular_cavariables in your inventory file.

The hawkular-metrics.pem value needs to contain the certificate in its .pem format. You may also need to provide the certificate for the Certificate Authority which signed this pem file via the hawkular-metrics-ca.cert secret.

For more information, please see the re-encryption route documentation.

31.6. DEPLOYING THE METRIC COMPONENTS

Because deploying and configuring all the metric components is handled with OpenShift Ansible, you can deploy everything in one step.

The following examples show you how to deploy metrics with and without persistent storage using the default parameters.

Example 31.3. Deploying with Persistent Storage

The following command sets the Hawkular Metrics route to use **hawkular-metrics.example.com** and is deployed using persistent storage.

You must have a persistent volume of sufficient size available.

```
$ ansible-playbook <OPENSHIFT_ANSIBLE_DIR>/byo/openshift-
cluster/openshift-metrics.yml \
   -e openshift_metrics_install_metrics=True \
   -e openshift_metrics_hawkular_hostname=hawkular-metrics.example.com \
```

Example 31.4. Deploying without Persistent Storage

-e openshift_metrics_cassandra_storage_type=pv

The following command sets the Hawkular Metrics route to use **hawkular-metrics.example.com** and deploy without persistent storage.

```
$ ansible-playbook <OPENSHIFT_ANSIBLE_DIR>/byo/openshift-
cluster/openshift-metrics.yml \
   -e openshift_metrics_install_metrics=True \
   -e openshift_metrics_hawkular_hostname=hawkular-metrics.example.com
```

WARNING

Because this is being deployed without persistent storage, metric data loss can

31.6.1. Metrics Diagnostics

The are some diagnostics for metrics to assist in evaluating the state of the metrics stack. To execute diagnostics for metrics:

\$ oadm diagnostics MetricsApiProxy

31.7. DEPLOYING THE HAWKULAR OPENSHIFT AGENT

NOTE

The Hawkular OpenShift Agent is currently in Technology Preview.

The Hawkular OpenShift Agent can be used to gather application metrics from pods running within the OpenShift Container Platform cluster. These metrics can then be viewed from the console or accessed via the Hawkular Metrics REST API.

In order for these metrics to be gathered, your pod needs to expose a Prometheus or Jolokia endpoint and create a special ConfigMap, which defines where the metric endpoint is located and how the metrics should be gathered. More information can be found under the Hawkular OpenShift Agent documentation.

The agent runs as a daemon set in your cluster and is deployed to the **default** project. By deploying to the **default** project, the agent continues to monitor all your pods even if the **ovs_multitenant** plug-in is enabled.

To deploy the agent, you will need to gather two configuration files:

```
$ wget https://github.com/openshift/origin-
metrics/blob/enterprise/hawkular-openshift-agent/hawkular-openshift-agent-
configmap.yaml
$ wget https://github.com/openshift/origin-
metrics/blob/enterprise/hawkular-openshift-agent/hawkular-openshift-
agent.yaml
```

To set up and deploy the agent into your OpenShift Container Platform cluster, run:

```
$ oc create -f hawkular-openshift-agent-configmap.yaml -n default
$ oc process -f hawkular-openshift-agent.yaml | oc create -n default -f -
$ oc adm policy add-cluster-role-to-user hawkular-openshift-agent
system:serviceaccount:default:hawkular-openshift-agent
```

31.7.1. Undeploying the Hawkular OpenShift Agent

To undeploy the Hawkular Metrics Agent, run:

\$ oc delete all,secrets,sa,templates,configmaps,daemonsets,clusterroles -selector=metrics-infra=agent -n default

31.8. SETTING THE METRICS PUBLIC URL

The OpenShift Container Platform web console uses the data coming from the Hawkular Metrics service to display its graphs. The URL for accessing the Hawkular Metrics service must be configured with the metricsPublicURL option in the master configuration file (/etc/origin/master/master-config.yaml). This URL corresponds to the route created with the openshift_metrics_hawkular_hostname inventory variable used during the deployment of the metrics components.

NOTE

You must be able to resolve the **openshift_metrics_hawkular_hostname** from the browser accessing the console.

For example, if your openshift_metrics_hawkular_hostname corresponds to hawkular-metrics.example.com, then you must make the following change in the *master-config.yaml* file:

```
assetConfig:
...
metricsPublicURL: "https://hawkular-
metrics.example.com/hawkular/metrics"
```

Once you have updated and saved the *master-config.yaml* file, you must restart your OpenShift Container Platform instance.

When your OpenShift Container Platform server is back up and running, metrics will be displayed on the pod overview pages.

CAUTION

If you are using self-signed certificates, remember that the Hawkular Metrics service is hosted under a different host name and uses different certificates than the console. You may need to explicitly open a browser tab to the value specified in metricsPublicURL and accept that certificate.

To avoid this issue, use certificates which are configured to be acceptable by your browser.

31.9. ACCESSING HAWKULAR METRICS DIRECTLY

To access and manage metrics more directly, use the Hawkular Metrics API.

NOTE

When accessing Hawkular Metrics from the API, you will only be able to perform reads. Writing metrics has been disabled by default. If you want for individual users to also be able to write metrics, you must set the

openshift_metrics_hawkular_user_write_accessvariable to true.

However, it is recommended to use the default configuration and only have metrics enter the system via Heapster. If write access is enabled, any user will be able to write metrics to the system, which can affect performance and cause Cassandra disk usage to unpredictably increase.

The Hawkular Metrics documentation covers how to use the API, but there are a few differences when dealing with the version of Hawkular Metrics configured for use on OpenShift Container Platform:

31.9.1. OpenShift Container Platform Projects and Hawkular Tenants

Hawkular Metrics is a multi-tenanted application. It is configured so that a project in OpenShift Container Platform corresponds to a tenant in Hawkular Metrics.

As such, when accessing metrics for a project named **MyProject** you must set the **Hawkular-Tenant** header to **MyProject**.

There is also a special tenant named **_system** which contains system level metrics. This requires either a **cluster-reader** or **cluster-admin** level privileges to access.

31.9.2. Authorization

The Hawkular Metrics service will authenticate the user against OpenShift Container Platform to determine if the user has access to the project it is trying to access.

Hawkular Metrics accepts a bearer token from the client and verifies that token with the OpenShift Container Platform server using a **SubjectAccessReview**. If the user has proper read privileges for the project, they are allowed to read the metrics for that project. For the _system tenant, the user requesting to read from this tenant must have cluster-reader permission.

When accessing the Hawkular Metrics API, you must pass a bearer token in the **Authorization** header.

31.10. SCALING OPENSHIFT CONTAINER PLATFORM CLUSTER METRICS PODS

Information about scaling cluster metrics capabilities is available in the Scaling and Performance Guide.

31.11. CLEANUP

You can remove everything deployed by the OpenShift Ansible **openshift_metrics** role by performing the following steps:

```
$ ansible-playbook <OPENSHIFT_ANSIBLE_DIR>/byo/openshift-
cluster/openshift-metrics.yml \
   -e openshift_metrics_install_metrics=False
```

CHAPTER 32. CUSTOMIZING THE WEB CONSOLE

32.1. OVERVIEW

Administrators can customize the web console using extensions, which let you run scripts and load custom stylesheets when the web console loads. Extension scripts allow you to override the default behavior of the web console and customize it for your needs.

For example, extension scripts can be used to add your own company's branding or to add company-specific capabilities. A common use case for this is rebranding or white-labelling for different environments. You can use the same extension code, but provide settings that change the web console. You can change the look and feel of nearly any aspect of the user interface in this way.

32.2. LOADING EXTENSION SCRIPTS AND STYLESHEETS

To add scripts and stylesheets, edit the master configuration file. The scripts and stylesheet files must exist on the Asset Server and are added with the following options:

```
assetConfig:
...
extensionScripts:
    -/path/to/script1.js
    -/path/to/script2.js
    -...
extensionStylesheets:
    -/path/to/stylesheet1.css
    -/path/to/stylesheet2.css
    -...
```

NOTE

Wrap extension scripts in an Immediately Invoked Function Expression (IIFE). This ensures that you do not create global variables that conflict with the names used by the web console or by other extensions. For example:

```
(function() {
  // Put your extension code here...
}());
```

Relative paths are resolved relative to the master configuration file. To pick up configuration changes, restart the server.

Custom scripts and stylesheets are read once at server start time. To make developing extensions easier, you can reload scripts and stylesheets on every request by enabling development mode with the following setting:

```
assetConfig:
...
extensionDevelopment: true
```

When set, the web console reloads any changes to existing extension script or stylesheet files when you refresh the page in your browser. You still must restart the server when adding new extension

stylesheets or scripts, however. This setting is only recommended for testing changes and not for production.

The examples in the following sections show common ways you can customize the web console.

NOTE

Additional extension examples are available in the OpenShift Origin repository on GitHub.

32.2.1. Setting Extension Properties

If you have a specific extension, but want to use different text in it for each of the environments, you can define the environment in the *master-config.yaml* file, and use the same extension script across environments. Pass settings from the *master-config.yaml* file to be used by the extension using the extensionProperties mechanism:

```
assetConfig:
    extensionDevelopment: true
    extensionProperties:
        doc_url: https://docs.openshift.com
        key1: value1
        key2: value2
    extensionScripts:
```

This results in a global variable that can be accessed by the extension, as if the following code was executed:

```
window.OPENSHIFT_EXTENSION_PROPERTIES = {
  doc_url: "https://docs.openshift.com",
  key1: "value1",
  key2: "value2",
}
```

32.3. CUSTOMIZING THE LOGO

The following style changes the logo in the web console header:

```
#header-logo {
  background-image: url("https://www.example.com/images/logo.png");
  width: 190px;
  height: 20px;
}
```

Replace the **example.com** URL with a URL to an actual image, and adjust the width and height. The ideal height is **20px**.

Save the style to a file (for example, logo.css) and add it to the master configuration file:

```
assetConfig:
...
extensionStylesheets:
- /path/to/logo.css
```

32.4. CHANGING LINKS TO DOCUMENTATION

Links to external documentation are shown in various sections of the web console. The following example changes the URL for two given links to the documentation:

```
window.OPENSHIFT_CONSTANTS.HELP['get_started_cli'] =
"https://example.com/doc1.html";
window.OPENSHIFT_CONSTANTS.HELP['basic_cli_operations'] =
"https://example.com/doc2.html";
```

Alternatively, you can change the base URL for all documentation links.

This example would result in the default help URL https://example.com/docs/welcome/index.html:

```
window.OPENSHIFT_CONSTANTS.HELP_BASE_URL = "https://example.com/docs/"; 1
```

The path must end in a /.

Save this script to a file (for example, help-links.js) and add it to the master configuration file:

```
assetConfig:
...
extensionScripts:
- /path/to/help-links.js
```

32.5. ADDING OR CHANGING LINKS TO DOWNLOAD THE CLI

The **About** page in the web console provides download links for the <u>command line interface (CLI)</u> tools. These links can be configured by providing both the link text and URL, so that you can choose to point them directly to file packages, or to an external page that points to the actual packages.

For example, to point directly to packages that can be downloaded, where the link text is the package platform:

```
window.OPENSHIFT_CONSTANTS.CLI = {
   "Linux (32 bits)": "https://<cdn>/openshift-client-tools-linux-
32bit.tar.gz",
   "Linux (64 bits)": "https://<cdn>/openshift-client-tools-linux-
64bit.tar.gz",
   "Windows": "https://<cdn>/openshift-client-tools-windows.zip",
   "Mac OS X": "https://<cdn>/openshift-client-tools-mac.zip"
};
```

Alternatively, to point to a page that links the actual download packages, with the **Latest Release** link text:

```
window.OPENSHIFT_CONSTANTS.CLI = {
   "Latest Release": "https://<cdn>/openshift-client-tools/latest.html"
};
```

Save this script to a file (for example, cli-links.js) and add it to the master configuration file:

```
assetConfig:
...
extensionScripts:
- /path/to/cli-links.js
```

32.5.1. Customizing the About Page

To provide a custom **About** page for the web console:

1. Write an extension that looks like:

```
angular
   .module('aboutPageExtension', ['openshiftConsole'])
   .config(function($routeProvider) {
        $routeProvider
        .when('/about', {
            templateUrl: 'extensions/about/about.html',
            controller: 'AboutController'
        });
    }
   );
   hawtioPluginLoader.addModule('aboutPageExtension');
```

2. Save the script to a file (for example, about/about.js).

- 3. Write a customized template.
 - a. Start from the version of about.html from the OpenShift Container Platform release you are using. Within the template, there are two angular scope variables available: version.master.openshift and version.master.kubernetes.
 - b. Save the custom template to a file (for example, about/about.html).
 - c. Modify the master configuration file:

```
assetConfig:
    ...
    extensionScripts:
        - about/about.js
    ...
    extensions:
        - name: about
        sourceDirectory: /path/to/about
```

32.6. CONFIGURING NAVIGATION MENUS

32.6.1. Top Navigation Dropdown Menus

The top navigation bar of the web console contains the help icon and the user dropdown menus. You can add additional menu items to these using the angular-extension-registry.

The available extension points are:

- nav-help-dropdown the help icon dropdown menu, visible at desktop screen widths
- nav-user-dropdown the user dropdown menu, visible at desktop screen widths
- nav-dropdown-mobile the single menu for top navigation items at mobile screen widths

The following example extends the nav-help-dropdown menu, with a name of <myExtensionModule>:

NOTE

<myExtensionModule> is a placeholder name. Each dropdown menu extension must be unique enough so that it does not clash with any future angular modules.

```
angular
  .module('<myExtensionModule>', ['openshiftConsole'])
  .run([
    'extensionRegistry',
   function(extensionRegistry) {
     extensionRegistry
        .add('nav-help-dropdown', function() {
          return [
           {
             type: 'dom',
             node: '<a href="http://www.example.com/report"</pre>
target="_blank">Report a Bug</a>'
           }, {
             type: 'dom',
             node: '' // If you want a
horizontal divider to appear in the menu
           }, {
             type: 'dom',
             node: '<a href="http://www.example.com/status"</pre>
target="_blank">System Status</a>'
         ];
       });
   }
  1);
hawtioPluginLoader.addModule('<myExtensionModule>');
```

32.6.2. Project Left Navigation

When navigating within a project, a menu appears on the left with primary and secondary navigation. This menu structure is defined as a constant and can be overridden or modified.

NOTE

Significant customizations to the project navigation may affect the user experience and should be done with careful consideration. You may need to update this customization in future upgrades if you modify existing navigation items.

1. Create the configuration scripts within a file (for example, navigation.js):

```
// Append a new primary nav item. This is a simple direct
navigation item
// with no secondary menu.
window.OPENSHIFT_CONSTANTS.PROJECT_NAVIGATION.push({
  label: "Dashboard",
                               // The text label
  iconClass: "fa fa-dashboard", // The icon you want to appear
  href: "/dashboard"
                              // Where to go when this nav item
is clicked.
                              // Relative URLs are pre-pended
with the path
                              // '/project/<project-name>'
});
// Splice a primary nav item to a specific spot in the list. This
primary item has
// a secondary menu.
window.OPENSHIFT_CONSTANTS.PROJECT_NAVIGATION.splice(2, 0, { //
Insert at the third spot
  label: "Git",
  iconClass: "fa fa-code",
  secondaryNavSections: [ // Instead of an href, a sub-menu
can be defined
    {
      items: [
          label: "Branches",
          href: "/git/branches",
          prefixes: [
            "/git/branches/" // Defines prefix URL patterns
that will cause
                                // this nav item to show the
active state, so
                                // tertiary or lower pages show
the right context
        }
      ]
    },
      header: "Collaboration", // Sections within a sub-menu can
have an optional header
      items: [
        {
          label: "Pull Requests",
          href: "/git/pull-requests",
          prefixes: [
            "/git/pull-requests/"
       }
      ]
    }
  1
});
```

```
// Add a primary item to the top of the list. This primary item is
shown conditionally.
window.OPENSHIFT_CONSTANTS.PROJECT_NAVIGATION.unshift({
  label: "Getting Started",
  iconClass: "pficon pficon-screen",
  href: "/getting-started",
  prefixes: [
                                // Primary nav items can also
specify prefixes to trigger
    "/getting-started/"
                                // active state
  ],
  isValid: function() {
                                // Primary or secondary items can
define an isValid
   return isNewUser;
                                // function. If present it will be
called to test whether
                                // the item should be shown, it
should return a boolean
 }
});
// Modify an existing menu item
var applicationsMenu =
_.find(window.OPENSHIFT_CONSTANTS.PROJECT_NAVIGATION, { label:
'Applications' });
applicationsMenu.secondaryNavSections.push({ // Add a new secondary
nav section to the Applications menu
  // my secondary nav section
});
```

2. Save the file and add it to the master configuration at /etc/origin/master/master-config.yml:

```
assetConfig:
    ...
    extensionScripts:
        - /path/to/navigation.js
```

3. Restart the master host:

```
# systemctl restart atomic-openshift-master
```

32.7. CONFIGURING CATALOG CATEGORIES

Catalog categories organize the display of builder images and templates on the **Add to Project** page on the OpenShift Container Platform web console. A builder image or template is grouped in a category if it includes a tag with the same name of the category or category alias. Categories only display if one or more builder images or templates with matching tags are present in the catalog.

NOTE

Significant customizations to the catalog categories may affect the user experience and should be done with careful consideration. You may need to update this customization in future upgrades if you modify existing category items.

Create the following configuration scripts within a file (for example, catalog-categories.js):

```
// Add Go to the Languages category
var category = _.find(window.OPENSHIFT_CONSTANTS.CATALOG_CATEGORIES,
{ id: 'languages' });
category.items.splice(2,0,{ // Insert at the third spot
  // Required. Must be unique
  id: "go",
 // Required
  label: "Go",
 // Optional. If specified, defines a unique icon for this item
  iconClass: "font-icon icon-go-gopher",
  // Optional. If specified, enables matching other tag values to
this category
 // item
  categoryAliases: [
    "golang"
  ]
});
// Add a Featured category section at the top of the catalog
window.OPENSHIFT_CONSTANTS.CATALOG_CATEGORIES.unshift({
  // Required. Must be unique
  id: "featured",
 // Required
  label: "Featured",
  // Optional. If specified, each item in the category will utilize
this icon
  // as a default
  iconClassDefault: "fa fa-code",
  items: [
    {
      // Required. Must be unique
      id: "go",
      // Required
      label: "Go",
      // Optional. If specified, defines a unique icon for this
item
      iconClass: "font-icon icon-go-gopher",
      // Optional. If specified, enables matching other tag values
to this
      // category item
      categoryAliases: [
        "golang"
      ],
      // Optional. If specified, will display below the item label
      description: "An open source programming language developed at
Google in " +
      "2007 by Robert Griesemer, Rob Pike, and Ken Thompson."
    },
      // Required. Must be unique
      id: "jenkins",
      // Required
      label: "Jenkins",
      // Optional. If specified, defines a unique icon for this
item
      iconClass: "font-icon icon-jenkins",
```

```
// Optional. If specified, will display below the item label
    description: "An open source continuous integration tool
written in Java."
    }
]
});
```

1. Save the file and add it to the master configuration at /etc/origin/master/master-config.yml:

```
assetConfig:
...
extensionScripts:
- /path/to/catalog-categories.js
```

Restart the master host:
 # systemctl restart atomic-openshift-master

32.8. CONFIGURING THE CREATE FROM URL NAMESPACE WHITELIST

Create from URL only works with image streams or templates from namespaces that have been explicitly specified in OPENSHIFT_CONSTANTS.CREATE_FROM_URL_WHITELIST. To add namespaces to the whitelist, follow these steps:

NOTE

openshift is included in the whitelist by default. Do not remove it.

1. Create the following configuration scripts within a file (for example, *create-from-url-whitelist.js*):

```
// Add a namespace containing the image streams and/or templates
window.OPENSHIFT_CONSTANTS.CREATE_FROM_URL_WHITELIST.push(
   'shared-stuff'
);
```

2. Save the file and add it to the master configuration file at /etc/origin/master/master-config.yml:

```
assetConfig:
...
extensionScripts:
- /path/to/create-from-url-whitelist.js
```

3. Restart the master host:

```
# systemctl restart atomic-openshift-master
```

32.8.1. Enabling Wildcard Routes

If you enabled wildcard routes for a router, you can also enable wildcard routes in the web console. This lets users enter hostnames starting with an asterisk like *.example.com when creating a route. To enable wildcard routes:

1. Save this script to a file (for example, enable-wildcard-routes.js):

```
window.OPENSHIFT_CONSTANTS.DISABLE_WILDCARD_ROUTES = false;
```

2. Add it to the master configuration file:

```
assetConfig:
...
extensionScripts:
- /path/to/enable-wildcard-routes.js
```

Learn how to configure HAProxy routers to allow wildcard routes.

If you enabled wildcard routes for a router, you can also enable wildcard routes in the web console. This lets users enter hostnames starting with an asterisk like *.example.com when creating a route. To enable wildcard routes:

1. Save this script to a file (for example, enable-wildcard-routes.js):

```
window.OPENSHIFT_CONSTANTS.DISABLE_WILDCARD_ROUTES = false;
```

2. Add it to the master configuration file:

```
assetConfig:
    ...
    extensionScripts:
        - /path/to/enable-wildcard-routes.js
```

Learn how to configure HAProxy routers to allow wildcard routes.

32.9. ENABLING FEATURES IN TECHNOLOGY PREVIEW

Sometimes features are available in Technology Preview. By default, these features are disabled and hidden in the web console.

Currently, there are no web console features in Technology Preview.

To enable a Technology Preview feature:

1. Save this script to a file (for example, tech-preview.js):

```
window.OPENSHIFT_CONSTANTS.ENABLE_TECH_PREVIEW_FEATURE.
<feature_name> = true;
```

2. Add it to the master configuration file:

```
assetConfig:
    ...
    extensionScripts:
        - /path/to/tech-preview.js
```

32.10. SERVING STATIC FILES

You can serve other files from the Asset Server as well. For example, you might want to make the CLI executable available for download from the web console or add images to use in a custom stylesheet.

Add the directory with the files you want using the following configuration option:

```
assetConfig:
...
extensions:
- name: images
sourceDirectory: /path/to/my_images
```

The files under the /path/to/my_images directory will be available under the URL /<context>/extensions/images in the web console.

To reference these files from a stylesheet, you should generally use a relative path. For example:

```
#header-logo {
   background-image: url("../extensions/images/my-logo.png");
}
```

32.10.1. Enabling HTML5 Mode

The web console has a special mode for supporting certain static web applications that use the HTML5 history API:

```
assetConfig:
    ...
    extensions:
        - name: my_extension
        sourceDirectory: /path/to/myExtension
        html5Mode: true
```

Setting html5Mode to true enables two behaviors:

- 1. Any request for a non-existent file under /<context>/extensions/my_extension/instead serves /path/to/myExtension/index.html rather than a "404 Not Found" page.
- 2. The element <base href="/"> will be rewritten in /path/to/myExtension/index.html to use the actual base depending on the asset configuration; only this exact string is rewritten.

This is needed for JavaScript frameworks such as AngularJS that require base to be set in index.html.

32.11. CUSTOMIZING THE LOGIN PAGE

You can also change the login page, and the login provider selection page for the web console. Run the following commands to create templates you can modify:

```
$ oadm create-login-template > login-template.html
$ oadm create-provider-selection-template > provider-selection-
template.html
```

Edit the file to change the styles or add content, but be careful not to remove any required parameters inside the curly brackets.

To use your custom login page or provider selection page, set the following options in the master configuration file:

```
oauthConfig:
...
templates:
login: /path/to/login-template.html
providerSelection: /path/to/provider-selection-template.html
```

Relative paths are resolved relative to the master configuration file. You must restart the server after changing this configuration.

When there are multiple login providers configured or when the alwaysShowProviderSelection option in the *master-config.yamI* file is set to true, each time a user's token to OpenShift Container Platform expires, the user is presented with this custom page before they can proceed with other tasks.

32.11.1. Example Usage

Custom login pages can be used to create Terms of Service information. They can also be helpful if you use a third-party login provider, like GitHub or Google, to show users a branded page that they trust and expect before being redirected to the authentication provider.

32.12. CUSTOMIZING THE OAUTH ERROR PAGE

When errors occur during authentication, you can change the page shown.

1. Run the following command to create a template you can modify:

```
$ oadm create-error-template > error-template.html
```

2. Edit the file to change the styles or add content.

You can use the **Error** and **ErrorCode** variables in the template. To use your custom error page, set the following option in the master configuration file:

```
oauthConfig:
...
templates:
error: /path/to/error-template.html
```

Relative paths are resolved relative to the master configuration file.

3. You must restart the server after changing this configuration.

32.13. CHANGING THE LOGOUT URL

You can change the location a console user is sent to when logging out of the console by modifying the logoutURL parameter in the /etc/origin/master/master-config.yaml file:

```
...
assetConfig:
  logoutURL: "http://www.example.com"
...
```

This can be useful when authenticating with Request Header and OAuth or OpenID identity providers, which require visiting an external URL to destroy single sign-on sessions.

32.14. CONFIGURING WEB CONSOLE CUSTOMIZATIONS WITH ANSIBLE

During advanced installations, many modifications to the web console can be configured using the following parameters, which are configurable in the inventory file:

- openshift_master_logout_url
- openshift_master_extension_scripts
- openshift_master_extension_stylesheets
- openshift_master_extensions
- openshift_master_oauth_template
- openshift_master_metrics_public_url
- openshift_master_logging_public_url

Example Web Console Customization with Ansible

```
# Configure logoutURL in the master config for console customization
# See:
https://docs.openshift.com/enterprise/latest/install_config/web_console_cu
stomization.html#changing-the-logout-url
#openshift_master_logout_url=http://example.com
# Configure extensionScripts in the master config for console
customization
# See:
https://docs.openshift.com/enterprise/latest/install_config/web_console_cu
stomization.html#loading-custom-scripts-and-stylesheets
#openshift_master_extension_scripts=
['/path/on/host/to/script1.js','/path/on/host/to/script2.js']
# Configure extensionStylesheets in the master config for console
customization
# See:
https://docs.openshift.com/enterprise/latest/install_config/web_console_cu
stomization.html#loading-custom-scripts-and-stylesheets
#openshift_master_extension_stylesheets=
['/path/on/host/to/stylesheet1.css','/path/on/host/to/stylesheet2.css']
# Configure extensions in the master config for console customization
https://docs.openshift.com/enterprise/latest/install_config/web_console_cu
stomization.html#serving-static-files
#openshift_master_extensions=[{'name': 'images', 'sourceDirectory':
'/path/to/my_images'}]
# Configure extensions in the master config for console customization
```

```
# See:
https://docs.openshift.com/enterprise/latest/install_config/web_console_cu
stomization.html#serving-static-files
#openshift_master_oauth_template=/path/on/host/to/login-template.html
# Configure metricsPublicURL in the master config for cluster metrics.
Ansible is also able to configure metrics for you.
# See:
https://docs.openshift.com/enterprise/latest/install_config/cluster_metric
s.html
#openshift_master_metrics_public_url=https://hawkular-
metrics.example.com/hawkular/metrics
# Configure loggingPublicURL in the master config for aggregate logging.
Ansible is also able to install logging for you.
https://docs.openshift.com/enterprise/latest/install_config/aggregate_logg
ing.html
#openshift_master_logging_public_url=https://kibana.example.com
```

CHAPTER 33. REVISION HISTORY: INSTALLATION AND CONFIGURATION

33.1. MON SEP 18 2017

Affected Topic	Description of Change
Setting up a Router → Using the F5 Router Plug-in	Added to the Prerequisites and Supportability section with supportability information.
Setting Up a Router → Using the F5 Router Plug-in	Added an F5 support statement
Securing the Registry	Updated commands for registry installation.
Extended Registry Configuration	Updated commands for registry installation and added steps to use a ConfigMap not secrets to override registry defaults.
Accessing the Registry	Updated commands for registry installation.

33.2. WED SEP 06 2017

Affected Topic	Description of Change
Aggregating Container Logs	Updated openshift-ansible playbook steps in the Troubleshooting Kibana section.
Advanced Installation	Clarified information about using a non-default registry and router in the Configuring a Registry Location section.
Using the Default HAProxy Router	Added information on needing separate DNS entries for routing shards to the Using Router Shards section.

33.3. MON AUG 28 2017

Affected Topic	Description of Change
Aggregating Container Logs	Corrected the link to the logging yaml file example in the Specifying Logging Ansible Variables section.
Master and Node Configuration	Expanded openshift_master_audit_config details.

Affected Topic	Description of Change
Installing a Cluster → Advanced Installation	Added openshift_master_audit_config details.
Configuring Azure Blob Storage for Integrated Docker Registry	Added an example for configuring Azure Blob Storage for OpenShift Integrated Docker Registry.

33.4. FRI AUG 25 2017

Affected Topic	Description of Change
Setting up the Registry → Deploying a Registry on Existing Clusters	Removed Technology Preview notice from the Deploying the Registry as a DaemonSet section.

33.5. FRI AUG 18 2017

Affected Topic	Description of Change
Installing a Cluster → Advanced Installation	Added openshift_hosted_metrics_deployer_version and openshift_hosted_logging_deployer_version parameter usage. (BZ#1475880)
Installing a Cluster → Disconnected Installation	Corrected tag version for the metrics-deployer and logging-deployer images. (BZ#1475880)

33.6. MON AUG 14 2017

Affected Topic	Description of Change
Advanced Installation	Added information on configuring the default ports used by the master API and web console.

33.7. TUE AUG 08 2017

Affected Topic	Description of Change
Configuring the SDN	Added information about configuring Neutron to the Using Flannel section.

Affected Topic	Description of Change
Router → Using the Default HAProxy Router	Added new section on how to manually redeploy the router certificates.

33.8. FRI JUL 28 2017

Affected Topic	Description of Change
Redeploying Certificates	Added the Redeploying a New etcd CAsection.

33.9. THU JUL 27 2017

Affected Topic	Description of Change
Installing a Cluster → Disconnected Installation	Added the openshift/hello-openshift dependency to the Syncing Repositories section.
Configuring Authentication and User Agent	Added a note about whitelisting users.
Installing a Cluster → Advanced Installation	Updated Section 2.6.8, "Known Issues" Known Issues] to remove yum remove steps and instead link to Uninstalling OpenShift Container Platform.
Working with HTTP Proxies	Added note box about the limitations of the `no_proxy' variable acceptability.
Installing a Cluster → Advanced Installation	Added the Configuring the Firewall section.
Downgrading OpenShift	Updated the downgrading steps for clarity.

33.10. WED JUL 12 2017

Affected Topic	Description of Change
Installing a Cluster → Host Preparation	Replaced the deprecated openshift_master_portal_net variable with openshift_portal_net .
Installing a Cluster → Advanced Installation	Replaced the deprecated openshift_master_portal_net variable with openshift_portal_net .

Affected Topic	Description of Change

33.11. FRI JUL 07 2017

Affected Topic	Description of Change
Installing a Cluster → Advanced Installation	
Installing a Cluster → Quick Installation	
Upgrading a Cluster → Manual In-place Upgrades	Added workaround for NO_PROXY issue. (BZ#1466783)
Upgrading a Cluster → Automated In-place Upgrades	

33.12. THU JUL 06 2017

Affected Topic	Description of Change
Enabling Controller- managed Attachment and Detachment	New topic on enabling controller-managed attachment and detachment.

33.13. TUE JUN 27 2017

Affected Topic	Description of Change
Configuring for AWS	Updated the Example AWS Configuration with Ansible to include information on using IAM profiles.
Upgrading a Cluster → Blue-Green Deployments	Added an example new_nodes host group to the Creating and Labeling Green Nodes section.

33.14. TUE JUN 13 2017

Affected Topic	Description of Change
Installing a Cluster → Advanced Installation	Added a step to verify that the etcd package is installed, if you installed multiple etcd hosts.

33.15. TUE JUN 06 2017

Affected Topic	Description of Change
Installing a Cluster → Advanced Installation	Added Configuring Certificate Validity section and related variables to the Cluster Variables table.

33.16. WED MAY 31 2017

Affected Topic	Description of Change
Syncing Groups With LDAP	Added Nested Membership Sync Example.
Configuring Persistent Storage → Persistent Storage Using Azure File	New topic on provisioning a OpenShift Container Platform cluster with persistent storage using Azure File.
Installing a Cluster → Installing a Stand-alone Deployment of OpenShift Container Registry	Updated to use OpenShift Container Registry name and add clarification on the distinction between Atomic Registry.

33.17. THU MAY 25 2017

Affected Topic	Description of Change
Upgrading a Cluster → Blue-Green Deployments	Added an animated graphic showing the blue-green deployment process.
Installing a Cluster → Advanced Installation	Fixed incorrect Ansible value to deployment_type.
Persistent Storage Examples → Complete Example Using Ceph RB	New Setting ceph-user-secret as Default for Projects section.

Affected Topic	Description of Change
Configuring Authentication and User Agent	Noted that after making changes to an identity provider, you must restart the master service for the changes to take effect.
Configuring Persistent Storage → Persistent Storage Using Azure Disk	Added the Prerequisites section.
Configuring For Azure	Added the The Azure Configuration File section and some file example fixes.
Working with HTTP Proxies	Added the Using Maven Behind a Proxy section.

33.18. MON MAY 15 2017

Affected Topic	Description of Change
Upgrading a Cluster → Overview	Added clarification that nodes and masters are forward and backward compatible across one minor version.
Master and Node Configuration	Added information about openshift_master_audit_config to the Audit Configuration section.

33.19. MON MAY 08 2017

Affected Topic	Description of Change
Installing a Cluster → Advanced Installation	Added a Configuring Deployment Type section.
	Updated the Configuring Schedulability on Masters section to note that masters are automatically marked unschedulable by default by the installer.
	Updated the Configuring Node Host Labels section to better describe the special region=infra label and to suggest configuring dedicated infrastructure nodes.

33.20. TUE MAY 02 2017

Affected Topic	Description of Change
Aggregating Container Logs	Noted that aggregated logging is only supported using the journald driver in Docker

Affected Topic	Description of Change
Installing a Cluster → Advanced Installation	In the Configuring Cluster Metrics section, updated the openshift_metrics_install_metrics=true to be openshift_hosted_metrics_deploy.
Aggregating Container Logs	Added that the openshift_logging role labels nodes as part of the installation process.

33.21. WED APR 12 2017

OpenShift Container Platform 3.5 Initial Release

Affected Topic	Description of Change
Installing a Cluster → Prerequisites	Specified the UDP for port 4789.
Installing a Cluster → Host Preparation	Added rhel-7-fast-datapath-rpms to the list of repositories to be enabled.
Installing a Cluster → Advanced Installation	In the Known Issues multiple masters discussion, included the docker-common package in the removal process, following a failed setup play.
	Added information about deploying metrics using the ansible role openshift_metrics.
Setting up the Registry → Extended Registry Configuration	Added details about mirroring of blobs.
Setting up a Router → Using the Default HAProxy Router	Added graphics to the Using Router Shards section.
	Added a new section about Setting the Maximum Number of Concurrent Connections.
Setting up a Router → Deploying a Customized HAProxy Router	Expanded details in the Rebuilding Your Router section.
Setting up a Router → Using the F5 Router Plug-in	Added the Finding the Hostname of the Routersection
	Specified that F5 virtual servers must be configured by users as a prerequisite.
Upgrading a Cluster → Performing Manual In- place Cluster Upgrades	Added rhel-7-fast-datapath-rpms to the list of repositories to be enabled.

Affected Topic	Description of Change
Upgrading a Cluster → Automated In-place Cluster Upgrades	Added the Customizing Upgrades With Ansible Hooks section.
	Added rhel-7-fast-datapath-rpms to the list of repositories to be enabled.
Redeploying Certificates	Updated for new set of playbooks and options.
Configuring Authentication and	Updated authentication proxy requirements in Request Header.
User Agent	Added information about the ability include a list of one or more GitHub teams to which a user must have membership in order to authenticate.
Configuring Persistent Storage → Persistent Storage Using GlusterFS	Added Container Native Storage Recommendations.
Configuring Persistent Storage → Dynamic Provisioning and Creating Storage Classes	Added information about Trident from NetApp.
Persistent Storage Examples → Complete Example of Dynamic Provisioning Using Dedicated GlusterFS	New topic with a full dynamic provisioning example using a dedicated Gluster cluster.
Configuring Native Container Routing	Separated the Configuring Native Container Routing content from the Configuring Route Timeouts topic.
Configuring for OpenStack	Added openshift_cloudprovider_openstack_domain_id and openshift_cloudprovider_openstack_domain_name to the list of configurable parameters.
Configuring Global Build Defaults and Overrides	Added information to the Manually Setting Global Build Defaults example about adding default resources to BuildConfig.
	Added and organized information on configuring global build overrides.
Aggregating Container Logs	Added content to reference Ansible Logging updates.
Aggregate Logging Sizing Guidelines	Added content to reference Ansible Logging updates.

Affected Topic	Description of Change
Enabling Cluster Metrics	Added metrics recommendations for OpenShift Container Platform version 3.5.
	Added more details to the Specifying Metrics Ansible Variables section.
	Added content on deploying the agent to the default project in the Deploying the Hawkular OpenShift Agent section.
